

The basis of Multivariable Calculus

If a function is continuous and differentiable, on a small enough interval, the function will approximate a line (i.e., a function of x).

A similar intuition applies to functions of more than one variable (but with a plane, cube, hypercube, etc.). However, in multivariable functions, we will have to sacrifice the ability to visualize it.

For example, in multiple dimensions, it is possible for there to be a function that is both strictly decreasing (in one dimension) and strictly increasing (in another dimension).

Some Functions and Sets

$$f(x, y) = x^2 - y^2$$

DOMAIN: $\{(x, y) \mid \exists f(x, y)\}$

RANGE: $\{f(x, y) \mid (x, y) \in \text{Dom}(f)\} = \mathbb{R}$

GRAPH: $\text{Graph}(f) = \{x, y, f(x, y) \mid x, y \in \text{Dom}(f)\}$. For example, $(1, 3, 4) \notin \text{Graph}(f)$ since $1^2 - 3^2 \neq 4$.

Examples

In \mathbb{R}^3 , in x, y, z coordinates, $z = 3$ is a plane defined as follows:

- Parallel to the xy plane.
- Passes through the point $(0, 0, 3)$.

Meanwhile, $y = 0$ would be a “wall” that passes through the origin that contains the line $y = 0$ in the xy plane.

Finally, $z = x + y + 1$ is a plane, as we can see below.

Visualizing a function of multiple variables

Consider the function $f(x, y) = x^2 - y^2$. We can try visualizing slices as follows:

- $f(-2, y) = 4 - y^2$
- $f(0, y) = -y^2$
- $f(2, y) = 4 - y^2$
- $f(x, -2) = x^2 + 4$
- $f(x, 0) = x^2$
- $f(x, 2) = x^2 + 4$

Alternatively, we can visualize via contour diagrams (i.e., everywhere that z is a certain value), as seen in mathematica as follows:

Contour Example

Consider the function $f(x, y) = y - 3x^2$. We want to find the contours.

For any c , we have that $c = y - 3x^3$, or $y = 3x^3 + c$. Therefore, every contour “looks like” $3x^3 + c$ for values of c . For example, in the following, we have $c = \{-2, -1, 0, 1, 2\}$

Distance

In \mathbb{R}^5 , let $p = (3, 1, 4, 1, 5)$, and $q = (1, 0, -2, 0, 2)$. Using the Euclidean metric, we can find the distance between p and q is $d(p, q) = ((3 - 1)^2 + (1 - 0)^2 + (4 - (-2))^2 + (1 - 0)^2 + (5 - 2)^2)^{1/2} = (4 + 1 + 36 + 1 + 9)^{1/2} = \sqrt{51} = 7.14$. We can also call this the 2-norm.

$$d(p, q) = \left(\sum_{k=1}^n (p_k - q_k)^2 \right)^{1/2}$$

Derivatives

To denote a derivative, we can't talk about one value, we must use a *partial* derivative, $\frac{\partial f}{\partial x}$, or $\frac{\partial f}{\partial y}$. The closeness of the contours specifies both resolution and steepness.

We can estimate slope by calculating the difference between two contours, divided by the distance between them along a path.

We can also analyze via a table:

$x \backslash y$	0	1	2
4	5	6	7
6	8	9	10
8	11	12	13

A “linear” approximation for a function of two variables is expressed as follows:

$$z - z_0 = m(x - x_0) + n(y - y_0)$$

Where $(x_0, y_0, z_0) \in \mathbb{R}^3$, and is an output in $z = f(x, y)$, and $m, n \in \mathbb{R}$.

For example, with the above table, we can see that the function is linear in x and y (i.e., the slope holding the other variable constant is constant).

Limits in Multivariable Functions

Consider the following:

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + y^2}{x^2 - y^2}$$

Allow $y = mx$

$$\begin{aligned}\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + y^2}{x^2 - y^2} &= \lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + (mx)^2}{x^2 - (mx)^2} \\ &= \frac{1 + m^2}{1 - m^2}\end{aligned}$$

Thus, the limit must depend on the path taken. The following table shows the limits for different values of m

m	$\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 + y^2}{x^2 - y^2}$
0	1
1	undefined
2	$-\frac{5}{3}$

Because the limit depends on the path of incidence, we have that the limit is **undefined**.

For graphs where the contours “approach” a particular point, we can see that the limit is defined.

Vectors

A vector is a mathematical object with direction and magnitude:

$$\vec{v} = \begin{bmatrix} 3 \\ 1 \\ 4 \end{bmatrix}$$

Alternatively, we can have $\vec{w} = [3 \quad 1 \quad 4]$. These vectors are equivalent because they are components of \mathbb{R}^3 .

Vector addition is *component-wise*, (i.e., you add or subtract components in order to find the new vectors).

Direction of \vec{v}

$$\frac{\vec{v}}{\|\vec{v}\|}$$

Properties of Vectors

Let $\vec{u}, \vec{v} \in \mathbb{R}^n$. Via properties of the real numbers, we know the following:

- $\vec{u} + \vec{v} = \vec{v} + \vec{u}$
- $(\vec{u} + \vec{v}) + \vec{w} = \vec{u} + (\vec{v} + \vec{w})$
- $c\vec{u} = \langle cu_1, cu_2, \dots, cu_k \rangle$

Additionally, we define $\vec{u} \cdot \vec{v}$ as follows:

$$\vec{u} \cdot \vec{v} = \sum_{k=1}^n u_k v_k = \|\vec{u}\| \|\vec{v}\| \cos \theta$$
