Introduction

Finally, the last part of my notes on C^* -algebras and amenability as part of my Honors Thesis independent study. Specifically, I am going to focus more on the theory of C^* -algebras, discussing ideas such as amenability and nuclearity in C^* -algebras. There are a few central results I'm going to be working on understanding and proving: almost-invariant vectors, Kesten's criterion, Hulanicki's criterion, nuclearity, and the equivalence of $C_\lambda^*(G)$ and $C^*(G)$.

I will be using a variety of sources more focused on amenability, including but not limited to Volker Runde's *Amenable Banach Algebras*, Kate Juschenko's *Amenability of Discrete Groups by Examples*, and Brown and Ozawa's *C^* -Algebras and Finite-Dimensional Approximations*.

Review: Representations, the Reduced Group C^* -Algebra, and the Universal Group C^* -Algebra

Left-Regular Representation

Let Γ be a group. Consider the space $\ell_2(\Gamma)$. For every $s \in \Gamma$, we define the operator

$$\lambda_s(\xi)(t) = \xi(s^{-1}t).$$

The map is linear, well-defined, and an isometry, as

$$\begin{aligned}\|\lambda_s(\xi)\|^2 &= \sum_{t \in \Gamma} |\lambda_s(\xi)(t)|^2 \\ &= \sum_{t \in \Gamma} |\xi(s^{-1}t)|^2 \\ &= \sum_{r \in \Gamma} |\xi(r)|^2 \\ &= \|\xi\|^2.\end{aligned}$$

Additionally, each λ_s admits an inverse, $\lambda_{s^{-1}} = \lambda_s^*$. Applying to the orthonormal basis $\{\delta_t\}_{t \in \Gamma}$, we get

$$\lambda_s(\delta_t) = \delta_{st}.$$

Thus, $\lambda_s \circ \lambda_r = \lambda_{sr}$, and we have the unitary representation of Γ , $\lambda: \Gamma \rightarrow \mathcal{U}(\ell_2(\Gamma))$, where $\lambda(s) = \lambda_s$, for $s \in \Gamma$. This is the left-regular representation of Γ .

Note that the left regular representation is a faithful representation, hence injective.

Because the λ operator is linear, we may extend it to the case of any positive finitely supported function,

$$\begin{aligned}\lambda_f(\xi)(t) &= \left(\sum_{s \in \Gamma} f(s) \lambda_s(\xi) \right)(t) \\ &= \sum_{s \in \Gamma} f(s) \xi(s^{-1}t)\end{aligned}$$

Note that the space of finitely supported functions on Γ , $\mathbb{C}[\Gamma]^I$ is a $*$ -algebra, where multiplication is given by convolution:

$$\begin{aligned}f * g(t) &= \sum_{s \in \Gamma} f(s) g(s^{-1}t) \\ &= \sum_{r \in \Gamma} f(tr^{-1}) g(r).\end{aligned}$$

Note that we are using $*$ both to refer to the involution (when as a superscript) as well as the group operation (when not a superscript). This is to maintain coherence with the traditional way that convolution is written. The involution on $\mathbb{C}[\Gamma]$ is given by

$$f^*(t) = \overline{f(t^{-1})}.$$

A Bit on Representations and C^* -(Semi)norms

A C^* -seminorm on a $*$ -algebra is a seminorm such that defined by

- $\|ab\| \leq \|a\| \|b\|$;
- $\|a^*\| = \|a\|$;
- $\|a^*a\| = \|a\|^2$.

If A_0 is a $*$ -algebra, then a representation of A_0 is a pair (π_0, \mathcal{H}) , where \mathcal{H} is a Hilbert space and $\pi: A_0 \rightarrow \mathcal{B}(\mathcal{H})$ is a $*$ -homomorphism.

^IAlso known as the free vector space over \mathbb{C} with basis Γ .

Additionally, if A_0 is a $*$ -algebra with representation π_0 , then we have C*-seminorm

$$\|a\|_{\pi_0} = \|\pi_0(a)\|_{\text{op}}.$$

If π_0 is injective, then $\|\cdot\|_{\pi_0}$ is a C*-norm. If π_0 is a C*-norm, then the completion of A_0 with respect to $\|\cdot\|_{\pi_0}$ is a C*-algebra.

The universal norm on A_0 is defined as

$$\|a\|_{\mathfrak{u}} = \sup_{p \in \mathcal{P}} p(a),$$

where \mathcal{P} is the collection of all C*-seminorms on A_0 . If $\|a\|_{\mathfrak{u}} < \infty$ for all $a \in A_0$, then $\|\cdot\|_{\mathfrak{u}}$ is a C*-seminorm on A_0 . Note that if one of $p \in \mathcal{P}$ is a norm, then $\|\cdot\|_{\mathfrak{u}}$ defines a C*-norm on A_0 .

If we have the unitary representation $u: \mathbb{C}[\Gamma] \rightarrow \mathbb{B}(\mathcal{H})$, then

$$\pi_u(a) = \sum_{s \in \Gamma} u_s$$

is a representation of $\mathbb{C}[\Gamma]$. If $\lambda: \Gamma \rightarrow \mathcal{U}(\ell_2(\Gamma))$ is the left-regular representation, then the left-regular group C*-algebra is the group $*$ -algebra with C*-norm defined by $\|a\| = \|\pi_\lambda(a)\|$.

The universal group C*-algebra is defined as the norm completion of

$$\|a\|_{\max} = \sup \left\{ \|\pi(a)\|_{\text{op}} \mid \pi: \mathbb{C}[\Gamma] \rightarrow \mathbb{B}(\mathcal{H}_\pi) \text{ is a representation} \right\}.$$

Note that

$$\begin{aligned} \|\pi(a)\| &= \left\| \pi \left(\sum_{s \in \Gamma} a_s \delta_s \right) \right\| \\ &= \left\| \sum_{s \in \Gamma} a_s \pi(\delta_s) \right\| \\ &\leq \sum_{s \in \Gamma} \|a_s \pi(\delta_s)\| \\ &= \sum_{s \in \Gamma} |a_s|. \end{aligned}$$

Note that since $\|\cdot\|_\lambda$ is a norm, we must have $a = 0$ if and only if $\|a\|_{\max} = 0$. The full group C*-algebra admits a universal property.

Proposition: Let Γ be a discrete group. If $u: \Gamma \rightarrow \mathbb{B}(\mathcal{H})$, then there is a contractive $*$ -homomorphism $\pi_u: C^*(\Gamma) \rightarrow \mathbb{B}(\mathcal{H})$ that satisfies $\pi_u(\delta_s) = u(s)$.

Using the Left-Regular Representation to Establish Amenability

If $\pi: \Gamma \rightarrow \mathcal{U}(\mathcal{H})$ is a unitary representation of Γ , then a vector $\xi \in \mathcal{H}$ is called invariant for π if $\pi(g)(\xi) = \xi$ for all $g \in \Gamma$.

Proposition: The left-regular representation for Γ admits an invariant vector if and only if Γ is finite.

Proof. Let Γ be finite. Since Γ is finite, all functions $a: \Gamma \rightarrow \mathbb{C}$ are square-summable. Thus, $\xi = \mathbb{1}_\Gamma$ is square-summable, and since $s\Gamma = \Gamma$ for all $s \in \Gamma$, we have $\mathbb{1}_\Gamma$ is invariant for λ .

Now, let $\lambda: \Gamma \rightarrow \mathcal{U}(\ell_2(\Gamma))$ be the left-regular representation, and suppose there is $\xi \in \ell_2(\Gamma)$ such that for all $s \in \Gamma$, we have

$$\lambda_s(\xi) = \xi.$$

In particular, this means that for any $t \in \Gamma$, we have

$$\begin{aligned}\lambda_s(\xi)(t) &= \xi(s^{-1}t) \\ &= \xi(t).\end{aligned}$$

Since this holds for all $s \in \Gamma$, we have that $\xi = c\mathbb{1}_\Gamma$ for some $c \in \mathbb{C}$. However, since $\xi \in \ell_2(\Gamma)$, we must have that $\sum_{t \in \Gamma} |c|^2 < \infty$, which only holds if Γ is finite. \square

An almost-invariant vector for a representation $\pi: \Gamma \rightarrow \mathcal{U}(\ell_2(\Gamma))$, as the name suggests,¹¹ a sequence (or net) of unit vectors $(\xi_i)_{i \in I}$ such that

$$\lim_{i \in I} \|\pi(g)(\xi_i) - \xi_i\| = 0.$$

Theorem: A group Γ is amenable if and only if the left-regular representation has an almost-invariant vector.

Proof. Let Γ be amenable, and let F_i be a Følner sequence, where $\frac{|sF_i \Delta F_i|}{|F_i|} \rightarrow 0$ for all $s \in \Gamma$.

Define $\xi_i = \frac{1}{\sqrt{|F_i|}} \mathbb{1}_{F_i}$. Then,

$$\begin{aligned}\|\lambda_s(\xi_i) - \xi_i\|^2 &= \sum_{t \in \Gamma} |\lambda_s(\xi_i)(t) - \xi_i(t)|^2 \\ &= \sum_{t \in \Gamma} \left| \lambda_s \left(\frac{1}{\sqrt{|F_i|}} \mathbb{1}_{F_i} \right) (t) - \frac{1}{\sqrt{|F_i|}} \mathbb{1}_{F_i}(t) \right|^2 \\ &= \sum_{t \in \Gamma} \left| \frac{1}{\sqrt{|F_i|}} \mathbb{1}_{sF_i}(t) - \frac{1}{\sqrt{|F_i|}} \mathbb{1}_{F_i}(t) \right|^2 \\ &= \frac{|sF_i \Delta F_i|}{|F_i|}.\end{aligned}$$

Thus, λ has an almost-invariant vector.

Suppose there exists an almost-invariant vector $(\xi_i)_i \in \ell_2(\Gamma)$. It is sufficient to construct an approximate mean. Since $\xi_i \in \ell_2(\Gamma)$, we have that $\xi_i^2 \in \ell_1(\Gamma)$. Setting $\mu_i = \xi_i^2$, we plug this into the expression for an approximate mean, and obtain

$$\begin{aligned}\|\lambda_s(\mu_i) - \mu_i\|_{\ell_1} &= \sum_{t \in \Gamma} \left| \lambda_s(\xi_i^2)(t) - \xi_i^2(t) \right| \\ &= \sum_{t \in \Gamma} |(\lambda_s(\xi_i)(t) - \xi_i(t))(\lambda_s(\xi_i)(t) + \xi_i(t))| \\ &= \|(\lambda_s(\xi_i) - \xi_i)(\lambda_s(\xi_i) + \xi_i)\|_{\ell_1} \\ &\leq \|\lambda_s(\xi_i) - \xi_i\|_{\ell_2} \|\lambda_s(\xi_i) + \xi_i\| \\ &\leq 2\|\lambda_s(\xi_i) - \xi_i\| \\ &\rightarrow 0.\end{aligned}$$

Thus, μ_i is an approximate mean. \square

¹¹I'm only mostly being facetious here.

Using the criterion of almost invariant vectors, we may show that a group is amenable if and only if the trivial representation — defined by $1_\Gamma: \Gamma \rightarrow \mathbb{C}$, $1_\Gamma(g) = 1$ is what is known as weakly contained in the left-regular representation.

A representation $\pi: \Gamma \rightarrow \mathcal{U}(\mathcal{H})$ is weakly contained in another representation $\rho: \Gamma \rightarrow \mathcal{U}(\mathcal{H})$, denoted $\pi < \rho$, if for every $\xi \in \mathcal{H}$, finite $E \subseteq \Gamma$, and $\varepsilon > 0$, then there are $\eta_1, \dots, \eta_n \in \mathcal{K}$ such that

$$\left| \langle \pi(g)(\xi), \xi \rangle - \sum_{i=1}^n \langle \rho(g)(\eta_i), \eta_i \rangle \right| < \varepsilon.$$

Theorem: A discrete group Γ is amenable if and only if $1_\Gamma < \lambda$, where λ is the left-regular representation.

Proof. We show that $1_\Gamma < \lambda$ is equivalent to the existence of an almost invariant vector for λ . We assume λ admits an almost-invariant vector. It is sufficient to show that for every $\varepsilon > 0$ and every finite set $E \subseteq \Gamma$, there are $\eta_1, \dots, \eta_n \in \ell_2(\Gamma)$ such that

$$\left| 1 - \sum_{i=1}^n \langle \lambda_t(\eta_i), \eta_i \rangle \right| < \varepsilon$$

for every $t \in E$. If we take $n = 1$ and $\eta_1 = \xi$, where ξ is almost-invariant for all $g \in E$ — i.e., $\|\lambda_g(\xi) - \xi\|_{\ell_2} < \varepsilon$ for all $g \in E$. Note that we have

$$\begin{aligned} \|\lambda_g(\xi) - \xi\|^2 &= \langle \lambda_g(\xi) - \xi, \lambda_g(\xi) - \xi \rangle \\ &= \langle \lambda_g(\xi), \lambda_g(\xi) \rangle + \langle \xi, \xi \rangle - 2 \operatorname{Re}(\langle \lambda_g(\xi), \xi \rangle) \\ &= 2 - 2 \operatorname{Re}(\langle \lambda_g(\xi), \xi \rangle) \\ &= 2 \operatorname{Re}(1 - \langle \lambda_g(\xi), \xi \rangle) \\ &\leq 2|1 - \langle \lambda_g(\xi), \xi \rangle|. \end{aligned}$$

Additionally,

$$\begin{aligned} |1 - \langle \lambda_g(\xi), \xi \rangle|^2 &= (1 - \langle \lambda_g(\xi), \xi \rangle)(1 - \overline{\langle \lambda_g(\xi), \xi \rangle}) \\ &= 1 - \overline{\langle \lambda_g(\xi), \xi \rangle} - \langle \lambda_g(\xi), \xi \rangle + |\langle \lambda_g(\xi), \xi \rangle|^2 \\ &\leq 2 - 2 \operatorname{Re}(\langle \lambda_g(\xi), \xi \rangle) \\ &= \|\lambda_g(\xi) - \xi\|^2. \end{aligned}$$

Thus, we have that

$$|1 - \langle \lambda_g(\xi), \xi \rangle| \leq \|\lambda_g(\xi) - \xi\| < \varepsilon.$$

We start by showing that $1_\Gamma < \lambda$ if and only if for every finite $S \subseteq \Gamma$ and every $\varepsilon > 0$, there exists a unit vector $\xi \in \mathcal{H}$ such that

$$\|\lambda_s(\xi) - \xi\|_{\ell_2} < \varepsilon.$$

In the forward direction, we see that there exists a unit vector ξ such that $|1 - \langle \lambda_s(\xi), \xi \rangle| < \varepsilon^2/2$, meaning $\|\lambda_s(\xi) - \xi\| < \varepsilon$ by above. Similarly, if $\|\lambda_s(\xi) - \xi\| < \varepsilon$, then $1_\Gamma < \lambda$.

Now, we assume $1_\Gamma < \lambda$. Thus, for a finite $E \subseteq \Gamma$ and $\varepsilon > 0$, then there exists $f \in \ell_2(\Gamma)$ with $\|f\|_{\ell_2} = 1$ such that $\|\lambda_s(f) - f\| < \varepsilon$ for all $s \in E$.

Setting $g = |f|^2$, we have $g \in \ell_1(\Gamma)$. From Hölder's inequality, we have

$$\begin{aligned} \|\lambda_s(g) - g\|_{\ell_1} &\leq \left\| \lambda_s(\tilde{f}) + \tilde{f} \right\|_{\ell_2} \|\lambda_s(f) - f\| \\ &\leq 2 \|\lambda_s(f) - f\|_{\ell_2} \\ &< 2\varepsilon. \end{aligned}$$

Thus, Γ admits an approximate mean, hence is amenable. \square

Having obtained some more resources on Kesten's criterion, we can now prove that.

Definition. Let $\lambda: \Gamma \rightarrow \mathcal{B}(\ell_2(\Gamma))$ be the left-regular representation. Then, for a finite set $E \subseteq \Gamma$, we define the Markov operator $M(E)$ by

$$M(E) = \sum_{t \in E} \lambda_t.$$

Note that since λ_t is an isometry for each t , we have

$$\begin{aligned} \|M(E)\|_{\text{op}} &= \left\| \frac{1}{|E|} \sum_{t \in E} \lambda_t \right\|_{\text{op}} \\ &= \frac{1}{|E|} \left\| \sum_{t \in E} \lambda_t \right\|_{\text{op}} \\ &\leq \frac{1}{|E|} \sum_{t \in E} \|\lambda_t\|_{\text{op}} \\ &= 1, \end{aligned}$$

so the Markov operator is a bounded operator (indeed, a contraction).

Theorem (Kesten's Criterion): Let Γ contain a finite symmetric generating set S . Then, Γ is amenable if and only if

$$\|M(S)\|_{\text{op}} = 1.$$

Proof. Let Γ be amenable. Then, λ admits an almost-invariant vector, $(\xi_n)_n \subseteq S_{\ell_2(\Gamma)}$, such that

$$\|\lambda_s(\xi_n) - \xi_n\|_{\ell_2} \rightarrow 0$$

for all $s \in \Gamma$. In particular, we have

$$\begin{aligned} \left| \left\| \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi_n) \right\|_{\ell_2} - \|\xi_n\|_{\ell_2} \right| &\leq \left\| \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi_n) - \xi_n \right\|_{\ell_2} \\ &= \frac{1}{|S|} \left\| \left(\sum_{t \in S} \lambda_t \right) (\xi_n) - |S| \xi_n \right\|_{\ell_2} \\ &\leq \frac{1}{|S|} \sum_{t \in S} \|\lambda_t(\xi_n) - \xi_n\|_{\ell_2} \\ &\rightarrow 0, \end{aligned}$$

meaning that

$$\sup_{\xi \in S_{\ell_2(\Gamma)}} \left\| \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi) \right\| = \|\xi\|,$$

and so the norm of the Markov operator is 1.

Suppose

$$\left\| \frac{1}{|S|} \sum_{t \in S} \lambda_t \right\|_{\text{op}} = 1,$$

or

$$\left\| \sum_{t \in S} \lambda_t \right\|_{\text{op}} = |S|.$$

Proposition: If $T \in \mathbb{B}(\mathcal{H})$ is a self-adjoint operator, then

$$\|T\|_{\text{op}} = \sup_{x \in S_{\mathcal{H}}} |\langle T(x), x \rangle|.$$

Proof. We have that

$$\begin{aligned} |\langle T(x), x \rangle| &\leq \|T(x)\| \|x\| \\ &\leq \|T\|_{\text{op}} \|x\|^2 \\ &= \|T\|_{\text{op}}. \end{aligned}$$

Now, we seek to establish the opposite direction. Note that since T is self-adjoint, we know that $\langle T(x), x \rangle \in \mathbb{R}$ for any $x \in \mathcal{H}$, so by the polarization identity, we have that

$$\langle T(x), y \rangle = \frac{1}{4} (\langle T(x+y), x+y \rangle - \langle T(x-y), x-y \rangle).$$

Note that we know that

$$\|T\|_{\text{op}} = \sup_{x, y \in S_{\mathcal{H}}} |\langle T(x), y \rangle|.$$

Now, we set $\alpha = \sup_{x \in S_{\mathcal{H}}} |\langle T(x), x \rangle|$. Note that for any nonzero $x \in \mathcal{H}$, we have

$$\begin{aligned} \left| \left\langle T\left(\frac{x}{\|x\|}\right), \frac{x}{\|x\|} \right\rangle \right| &\leq \alpha \\ |\langle T(x), x \rangle| &\leq \alpha \|x\|^2. \end{aligned}$$

Now, for any $x, y \in \mathcal{H}$, we may assume that $\langle T(x), y \rangle \in \mathbb{R}$, as we may multiply $\langle T(x), y \rangle$ by $\text{sgn}(\langle T(x), y \rangle)$. Thus, by the polarization identity and the fact that T is self-adjoint, we have

$$\begin{aligned} \langle T(x), y \rangle &= \frac{1}{4} (\langle T(x+y), x+y \rangle - \langle T(x-y), x-y \rangle) \\ |\langle T(x), y \rangle| &= \left| \frac{1}{4} (\langle T(x+y), x+y \rangle - \langle T(x-y), x-y \rangle) \right| \\ &\leq \frac{1}{4} (|\langle T(x+y), x+y \rangle| + |\langle T(x-y), x-y \rangle|) \\ &\leq \frac{\alpha}{4} (\|x+y\|^2 + \|x-y\|^2) \\ &= \frac{\alpha}{4} (2\|x\|^2 + 2\|y\|^2) \\ &= \alpha. \end{aligned}$$

Thus, we have $\|T\|_{\text{op}} \leq \sup_{x \in S_{\mathcal{H}}} |\langle T(x), x \rangle|$.

□

Now, since S is symmetric, we have that $M(S)$ is self-adjoint. Therefore, we know that there is some $\xi_n \in S_{\mathcal{H}}$ such that

$$\begin{aligned} 1 - \frac{1}{n} &< \left\langle \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi_n), \xi_n \right\rangle \\ &\leq \left\langle \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (|\xi_n|), |\xi_n| \right\rangle. \end{aligned}$$

Thus, rearranging, we have

$$1 - \left\langle \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (|\xi_n|), |\xi_n| \right\rangle < \frac{1}{n}.$$

Since $M(S)$ is a self-adjoint operator, we have that $\operatorname{Re} \left(\left\langle \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi_n), \xi_n \right\rangle \right) = \left\langle \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi_n), \xi_n \right\rangle$. This gives

$$\begin{aligned} \left\| \left(\frac{1}{|S|} \sum_{t \in S} \lambda_t \right) (\xi) - \xi \right\| &\leq \frac{1}{|S|} \sum_{t \in S} \|\lambda_t(\xi) - \xi\| \\ &\leq \frac{1}{|S|} \sum_{t \in S} \sqrt{2} |1 - \langle \lambda_t(\xi), \xi \rangle| \\ &= \sqrt{2} \left| 1 - \frac{1}{|S|} \sum_{t \in S} \langle \lambda_t(\xi), \xi \rangle \right| \\ &\rightarrow 0. \end{aligned}$$

Thus, λ admits an almost-invariant vector. □

Next, we turn to Hulanicki's Criterion.

Definition. Let $f \in \ell_1(\Gamma)$. Then, we define the bounded operator

$$\lambda_{f(t)} = \sum_{t \in \Gamma} f(t) \lambda_t.$$

Theorem: If Γ is a discrete group, then Γ is amenable if and only if for every positive finitely-supported $f: \Gamma \rightarrow \mathbb{C}$, we have

$$\sum f(t) \leq \|\lambda_{f(t)}\|_{\text{op}}.$$

Proof. Suppose Γ is amenable. Let $f \geq 0$ be a finitely supported function, and let $(F_n)_n$ be a Følner sequence such that for every $g \in \operatorname{supp}(f)$, we have

$$\frac{|g F_n \Delta F_n|}{|F_n|} \leq \frac{1}{n}.$$

Let $\xi_n = \frac{1}{\sqrt{|F_n|}} \mathbb{1}_{F_n}$. Note that $\|\xi_n\|_{\ell_2} = 1$.

We will use the fact that

$$\sup_{x \in S_{\mathcal{H}}} |\langle T(x), x \rangle| \leq \|T\|_{\text{op}}.$$

We see that

$$\begin{aligned} \left| \left\langle \left(\sum_{t \in \Gamma} f(t) \lambda_t \right) (\xi_n), \xi_n \right\rangle \right| &= \left| \sum_{t \in \Gamma} f(t) \langle \lambda_t (\xi_n), \xi_n \rangle \right| \\ &= \left| \sum_{t, s \in \Gamma} f(t) \xi_n(t^{-1}s) \xi_n(s) \right| \\ &\leq \| \lambda_{f(t)} \|, \end{aligned}$$

meaning

$$\lim_{n \rightarrow \infty} \left| \left\langle \left(\sum_{t \in \Gamma} f(t) \lambda_t \right) (\xi_n), \xi_n \right\rangle \right| \leq \| \lambda_{f(t)} \|.$$

Notice that ξ_n is an almost-invariant vector for λ , meaning that $\xi_n(t^{-1}s) \rightarrow \xi_n(s)$. Therefore, this means

$$\begin{aligned} \lim_{n \rightarrow \infty} \left| \sum_{t, s \in \Gamma} f(t) \xi_n(t^{-1}s) \xi_n(s) \right| &= \lim_{n \rightarrow \infty} \left| \sum_{t, s \in \Gamma} f(t) |\xi_n(s)|^2 \right| \\ &= \sum_{t \in \Gamma} f(t) \left| \sum_{s \in \Gamma} |\xi_n(s)|^2 \right| \\ &= \sum_{t \in \Gamma} f(t) \\ &\leq \| \lambda_{f(t)} \|_{\text{op}}. \end{aligned}$$

This establishes that there is some $C > 0$ such that

$$\sum_{t \in \Gamma} f(t) \leq C \| \lambda_{f(t)} \|_{\text{op}}.$$

To show that $C = 1$, we note that, by the definition of convolution, we must have

$$\left(\sum_{t \in \Gamma} f(t) \right)^n = \sum_{t \in \Gamma} (f * \dots * f)(t),$$

and

$$\begin{aligned} (\lambda_{f(t)})^n &= \left(\sum_{t \in \Gamma} f(t) \lambda_t \right)^n \\ &= \sum_{t \in \Gamma} (f * \dots * f)(t) \lambda_t \\ &= \lambda_{(f * \dots * f)(t)}. \end{aligned}$$

Thus, we have

$$\begin{aligned} \left(\sum_{t \in \Gamma} f(t) \right)^n &= \sum_{t \in \Gamma} (f * \dots * f)(t) \\ &\leq C \| \lambda_{(f * \dots * f)(t)} \| \\ &= C \left(\| \lambda_{f(t)} \|_{\text{op}} \right)^n. \end{aligned}$$

This means we have

$$\sum_{t \in \Gamma} f(t) \leq C^{1/n} \|\lambda_{f(t)}\|_{\text{op}}.$$

Since n is arbitrary, this means $C = 1$.

Now, if for all finitely supported f , we have

$$\sum_{t \in \Gamma} f(t) \leq \|\lambda_{f(t)}\|_{\text{op}}.$$

If $f = \mathbb{1}_E$ for some finite $E \subseteq \Gamma$, we see that

$$\left\| \sum_{t \in E} \lambda_t \right\|_{\text{op}} = |E|,$$

so by Kesten's criterion, we have that Γ is amenable. \square

Completely [Property] Maps

We begin this section with an overview of positive maps, completely positive maps, and extensions. These will be useful for understanding the theorem that a group is amenable if and only if the reduced group C^* -algebra is nuclear. The ultimate goal here is to prove Arveson's extension theorem (i.e., that $\mathbb{B}(\mathcal{H})$ is injective with respect to completely positive maps). The primary text for this purpose will be Vern Paulsen's *Completely Bounded Maps and Operator Algebras*.

The idea behind completely positive maps is that they are positive when subjected to a certain amplification process related to the matrix algebras.

Definition. An element of a C^* -algebra is positive if and only if it is self-adjoint and its spectrum is contained in the nonnegative reals. Alternatively, $b \in A$ is of the form $b = a^*a$ for some $a \in A$.

To introduce a norm such that $\text{Mat}_n(A)$ becomes a C^* -algebra, we begin with the most basic C^* -algebra, $\mathbb{B}(\mathcal{H})$, and consider the n -fold amplification of \mathcal{H} , $\mathcal{H}^{(n)}$. This is a Hilbert space equipped with inner product

$$\left\langle \begin{pmatrix} h_1 \\ \vdots \\ h_n \end{pmatrix}, \begin{pmatrix} k_1 \\ \vdots \\ k_n \end{pmatrix} \right\rangle = \sum_{j=1}^n \langle h_j, k_j \rangle.$$

Meanwhile, we may consider $\text{Mat}_n(\mathbb{B}(\mathcal{H}))$ as a linear map on $\mathcal{H}^{(n)}$, by taking

$$(T_{ij})_{ij} = \begin{pmatrix} \sum_{j=1}^n T_{1j}(h_j) \\ \vdots \\ \sum_{j=1}^n T_{nj}(h_j) \end{pmatrix}.$$

This yields a $*$ -isomorphism between $\text{Mat}_n(\mathbb{B}(\mathcal{H}))$ and $\mathbb{B}(\mathcal{H}^{(n)})$.

Given any C^* -algebra A , we may theorize $\text{Mat}_n(A)$ by first isometrically representing A on some Hilbert space \mathcal{H} , letting A be a C^* -subalgebra of $\mathbb{B}(\mathcal{H})$, and then identifying $\text{Mat}_n(A)$ as a $*$ -subalgebra of $\text{Mat}_n(\mathbb{B}(\mathcal{H}))$.

Using a faithful $*$ -representation of A , we now have a way to turn $\text{Mat}_n(A)$ into a C^* -algebra. However, since the norm is unique on a C^* -algebra, the norm on $\text{Mat}_n(A)$ defined in this fashion is independent of

the representation of A that we choose. Furthermore, since $*$ -isomorphisms are positive maps, the positive elements of $\text{Mat}_n(A)$ are uniquely determined. This means that every C^* -algebra carries with it a set of canonically defined norms and orders on each $\text{Mat}_n(A)$.

For example, consider $\text{Mat}_k(\mathbb{C})$, which can be identified with $\mathcal{L}(\mathcal{C}^k)$. We identify $\text{Mat}_n(\text{Mat}_k(\mathbb{C})) \cong \text{Mat}_{nk}(\mathbb{C})$. With this identification, the usual multiplication and involution on $\text{Mat}_n(\text{Mat}_k(\mathbb{C}))$ become multiplication and involution on $\text{Mat}_{nk}(\mathbb{C})$.

Now, let X be a compact Hausdorff space, and let $C(X)$ be the C^* -algebra of continuous functions with $f^*(x) = \overline{f(x)}$, equipped with the norm $\|f\| = \sup_{x \in X} |f(x)|$. Then, an element $F = (f_{ij})_{ij}$ of $\text{Mat}_n(C(X))$ can be considered as a continuous $\text{Mat}_n(\mathbb{C})$ -valued function. Addition, multiplication, and involution in $\text{Mat}_n(C(X))$ are pointwise. Recalling that the norm on $\text{Mat}_n(C(X))$ is unique, we may let $\|F\| = \sup_{x \in X} \|F(x)\|$, where the latter norm is the canonical matrix norm on $\text{Mat}_n(\mathbb{C})$. The positive elements of $\text{Mat}_n(C(X))$ are those F for which $F(x)$ is a positive matrix for all x .

Now, given two C^* -algebras A and B and a map $\phi: A \rightarrow B$, there are maps $\phi_n: \text{Mat}_n(A) \rightarrow \text{Mat}_n(B)$, given by

$$\phi_n\left((a_{ij})_{ij}\right) = (\phi(a_{ij}))_{ij}.$$

In general, when we say that ϕ is completely [property], then we say that all the ϕ_n have that property. For instance, if ϕ is positive, in that it maps positive elements of A to positive elements of B , then we say ϕ is completely positive if ϕ_n is a positive map for each n , where the positive elements of $\text{Mat}_n(A)$ and $\text{Mat}_n(B)$ are defined canonically.

Unfortunately, it's not always the case that (e.g.) positive maps are completely positive, or even that $\|\phi_n\|_{\text{op}} = \|\phi\|_{\text{op}}$ for each n .

There is an isomorphism between $\text{Mat}_n(A)$ and the tensor product $\text{Mat}_n(\mathbb{C}) \otimes A$. We detail it here. The proof is from Timothy Rainone's *Functional Analysis-En Route to Operator Algebras*.

Theorem: Let A be an algebra, and let $\text{Mat}_n(A)$ denote the matrix algebra of A . Then, there is a $*$ -isomorphism

$$\text{Mat}_n(A) \cong \text{Mat}_n(\mathbb{C}) \otimes A.$$

Proof. Define $\varphi: \text{Mat}_n(A) \rightarrow \text{Mat}_n(\mathbb{C}) \otimes A$ by

$$\varphi\left((a_{ij})_{ij}\right) = \sum_{i,j=1}^n e_{ij} \otimes a_{ij}.$$

Recall that if A and B are two algebras, multiplication in $A \otimes B$ is defined by

$$(a \otimes b)(c \otimes d) = ac \otimes bd,$$

and if A and B are $*$ -algebras, then the involution is defined by

$$(a \otimes b)^* = a^* \otimes b^*.$$

We start by showing that $\text{Mat}_n(A) \cong \text{Mat}_n(\mathbb{C}) \otimes A$ as vector spaces. By the definition of the tensor product, the map φ is linear.

Now, suppose

$$\varphi\left((a_{ij})_{ij}\right) = \sum_{i,j=1}^n e_{ij} \otimes a_{ij}$$

$$= 0.$$

Then, since $\{e_{ij}\}_{i,j}$ is linearly independent, we know that $x_{ij} = 0$ for all i, j , so $(a_{ij})_{ij} = 0$, so φ is injective.

Now, let $t \in \text{Mat}_n(\mathbb{C}) \otimes A$ be given by

$$t = \sum_k m_k \otimes a_k,$$

where $m_k \in \text{Mat}_n(\mathbb{C})$ and $a_k \in A$. Then, using the matrix units, we write each m_k as

$$m_k = \sum_{i,j=1}^n m_k(i,j) e_{ij}.$$

This gives

$$\begin{aligned} t &= \sum_k \left(\sum_{i,j=1}^n m_k(i,j) e_{ij} \right) \otimes a_k \\ &= \sum_{i,j=1}^n e_{ij} \otimes \left(\sum_k m_k(i,j) a_k \right). \end{aligned}$$

Defining $a_{ij} := \sum_k m_k(i,j) a_k$, we get

$$t = \sum_{i,j=1}^n e_{ij} \otimes a_{ij},$$

meaning that

$$\varphi\left((x_{ij})_{ij}\right) = t.$$

Thus, φ is surjective.

We will show now that φ is multiplicative and $*$ -preserving. If $(a_{ij})_{ij}$ and $(b_{ij})_{ij}$ belong to $\text{Mat}_n(A)$.

$$\begin{aligned} \varphi((a_{ik})_{ik}) \varphi((b_{lj})_{lj}) &= \left(\sum_{i,k=1}^n e_{ik} \otimes a_{ik} \right) \left(\sum_{l,j=1}^n e_{lj} \otimes b_{lj} \right) \\ &= \sum_{i,j,k,l=1}^n (e_{ik} \otimes a_{ik}) (e_{lj} \otimes b_{lj}) \\ &= \sum_{i,j,k,l=1}^n e_{ik} e_{lj} \otimes a_{ik} b_{lj} \\ &= \sum_{i,j,k=1}^n e_{ik} e_{kj} \otimes a_{ik} b_{kj} \\ &= \sum_{i,j,k=1}^n e_{ij} \otimes a_{ik} b_{kj} \\ &= \sum_{i,j=1}^n e_{ij} \otimes \left(\sum_{k=1}^n a_{ik} b_{kj} \right) \end{aligned}$$

$$\begin{aligned}
&= \varphi \left(\left(\sum_{k=1}^n a_{ik} b_{kj} \right)_{ij} \right) \\
&= \varphi \left((a_{ij})_{ij} (b_{ij})_{ij} \right).
\end{aligned}$$

Similarly,

$$\begin{aligned}
\varphi \left((a_{ij})_{ij} \right)^* &= \left(\sum_{i=1}^n e_{ij} \otimes a_{ij} \right)^* \\
&= \sum_{i,j=1}^n (e_{ij} \otimes a_{ij})^* \\
&= \sum_{i,j=1}^n e_{ij}^* \otimes a_{ij}^* \\
&= \sum_{i,j=1}^n e_{ji} \otimes a_{ij}^* \\
&= \sum_{i,j=1}^n e_{ij} \otimes a_{ji}^* \\
&= \varphi \left((a_{ji}^*)_{ij} \right) \\
&= \varphi \left((a_{ij})_{ij}^* \right).
\end{aligned}$$

□

There are lots of useful results using amplification to the matrix algebras.

Example (Dilating an Isometry). Let V be an isometry, and let $P = I_{\mathcal{H}} - VV^*$ be the projection onto $\text{Ran}(V)^\perp$. Define U on $\mathcal{K} = \mathcal{H} \oplus \mathcal{H}$ by

$$U = \begin{pmatrix} V & P \\ 0 & V^* \end{pmatrix}.$$

We find that

$$\begin{aligned}
U^* &= \begin{pmatrix} V^* & 0 \\ P & V \end{pmatrix} \\
UU^* &= \begin{pmatrix} V & P \\ 0 & V^* \end{pmatrix} \begin{pmatrix} V^* & 0 \\ P & V \end{pmatrix} \\
&= \begin{pmatrix} VV^* + P & PV \\ V^*P & V^*V \end{pmatrix} \\
&= \begin{pmatrix} I_{\mathcal{H}} & 0 \\ 0 & I_{\mathcal{H}} \end{pmatrix} \\
&= I_{\mathcal{K}} \\
U^*U &= \begin{pmatrix} V^* & 0 \\ P & V \end{pmatrix} \begin{pmatrix} V & P \\ 0 & V^* \end{pmatrix} \\
&= I_{\mathcal{K}}.
\end{aligned}$$

Thus, U is a unitary on \mathcal{K} . We may identify $\mathcal{H} \cong \mathcal{H} \oplus 0$, and take

$$V^n = P_{\mathcal{H}} U^n|_{\mathcal{H}}$$

for all $n \geq 0$. Thus, we are able to realize any isometry V as the restriction of some unitary to a subspace that respects powers.

Example (Dilating a Contraction). Similarly, we may define the isometric dilation of a contraction. Let T be an operator on \mathcal{H} with $\|T\| \leq 1$, and define $D_T = (I - T^*T)^{1/2}$. We see that

$$\begin{aligned} \|T(h)\|^2 + \|D_T(h)\|^2 &= \langle T^*T(h), h \rangle + \langle D_T^2(h), h \rangle \\ &= \|h\|^2. \end{aligned}$$

We consider now the sequence space

$$\ell_2(\mathcal{H}) = \left\{ (h_n)_{n \in \mathbb{N}} \mid h_n \in \mathcal{H}, \sum_{n=1}^{\infty} \|h_n\|^2 < \infty \right\}.$$

We have the norm

$$\|(h_n)_n\|^2 = \sum_{n=1}^{\infty} \|h_n\|^2$$

and the inner product

$$\langle (h_n)_n, (k_n)_n \rangle = \sum_{n=1}^{\infty} \langle h_n, k_n \rangle.$$

We define the operator $V: \ell_2(\mathcal{H}) \rightarrow \ell_2(\mathcal{H})$ by

$$V((h_n)_n) = (T(h_1), D_T(h_1), h_2, \dots).$$

It then follows that V is an isometry on $\ell_2(\mathcal{H})$, and that if we identify $\mathcal{H} \cong \mathcal{H} \oplus 0 \oplus \dots$, then $T^n = P_{\mathcal{H}} V^n|_{\mathcal{H}}$.

Theorem (Sz.-Nagy's Dilation Theorem): Let T be a contraction operator on \mathcal{H} . There is a Hilbert space \mathcal{K} containing \mathcal{H} as a subspace, and a unitary operator U on \mathcal{K} such that $T^n = P_{\mathcal{H}} U^n|_{\mathcal{H}}$.

Proof. Take $\mathcal{K} = \ell_2(\mathcal{H}) \oplus \ell_2(\mathcal{H})$, and identify \mathcal{H} as $(\mathcal{H} \oplus 0 \oplus \dots) \oplus 0$. Let V be the isometric dilation of T on $\ell_2(\mathcal{H})$, and let U be the unitary dilation of V on $\ell_2(\mathcal{H}) \oplus \ell_2(\mathcal{H})$. Then, since $\mathcal{H} \subseteq \ell_2(\mathcal{H}) \oplus 0$, we have that $P_{\mathcal{H}} U^n|_{\mathcal{H}} = P_{\mathcal{H}} V^n|_{\mathcal{H}} = T^n$ for all $n \geq 0$. \square

Whenever Y is an operator on \mathcal{K} , \mathcal{H} a (closed) subspace of \mathcal{K} , and $X = P_{\mathcal{H}} Y|_{\mathcal{H}}$, then we say X is a compression of Y .

Corollary (Von Neumann's Inequality): Let T be a contraction on a Hilbert space. Then, for any polynomial p ,

$$\|p(T)\| \leq \sup_{|z| \leq 1} |p(z)|.$$

Proof. Let U be a unitary dilation of T . Since $T^n = P_{\mathcal{H}} U^n|_{\mathcal{H}}$, linearity means we have $p(T) = P_{\mathcal{H}} p(U)|_{\mathcal{H}}$. Since U is defined on a larger space than T , then $\|p(T)\| \leq \|p(U)\|$. Furthermore, since unitaries are normal, we have

$$\|p(U)\| = \sup_{\lambda \in \sigma(U)} |p(\lambda)|,$$

where $\sigma(U)$ is the spectrum of U . Since U is unitary, $\sigma(U) \subseteq \mathbb{T}$, so von Neumann's inequality follows. \square

Positive and Completely Positive Maps

Positive Maps

There are certain results on positive maps that are useful in the study of completely positive maps. We introduce them here.

Definition. If S is a subset of a C^* -algebra A , we say S is an operator system if A is unital and S is a self-adjoint subspace of A with $1_A \in S$.

Note that if S is an operator system and $h \in S$ is self-adjoint, then though the values h_+ and h_- , defined by the continuous functional calculus with

$$f^+(x) = \max\{0, x\}$$

$$f^-(x) = \min_{0, -x}$$

may not belong to S , we can write h as the difference of two positive elements in S by

$$h = \frac{1}{2}(\|h\|1_A + h) - \frac{1}{2}(\|h\|1_A - h).$$

Definition. If S is an operator system, B is a C^* -algebra, and $\phi: S \rightarrow B$ is a linear map, then ϕ is called positive if it maps positive elements of S to positive elements of B .

Theorem: If ϕ is a positive linear functional on an operator system S , then $\|\phi\| = \phi(1_A)$.

When the range of ϕ is not \mathbb{C} , but rather a C^* -algebra, then the situation is a bit different.

Proposition: Let S be an operator system, and let B be a C^* -algebra. If $\phi: S \rightarrow B$ is a positive map, then ϕ is bounded, with

$$\|\phi\| \leq 2\|\phi(1_A)\|.$$

Proof. Note that if p is positive, then $0 \leq p \leq \|p\|1_A$, so $0 \leq \phi(p) \leq \|p\|\phi(1_A)$ since positive functions are order-preserving. Thus, we get $\|\phi(p)\| \leq \|p\|\|\phi(1)\|$ when $p \geq 0$.

Note that when p_1 and p_2 are positive, then $\|p_1 - p_2\| \leq \max\{\|p_1\|, \|p_2\|\}$. If h is self-adjoint, then we have

$$\|\phi(h)\| = \frac{1}{2}\|\phi(\|h\|1_A + h)\| - \frac{1}{2}\|\phi(\|h\|1_A - h)\|,$$

which is the difference of two positive elements in B . Thus, we have

$$\begin{aligned} \|\phi(h)\| &\leq \frac{1}{2} \max\{\|\phi(\|h\|1_A + h)\|, \|\phi(\|h\|1_A - h)\|\} \\ &\leq \|h\|\|\phi(1)\|. \end{aligned}$$

Finally, if a is arbitrary then write $a = h + ik$ via the Cartesian decomposition, where $\|h\|, \|k\| \leq \|a\|$, and h, k are self-adjoint. Thus, we have

$$\begin{aligned} \|\phi(a)\| &\leq \|\phi(h)\| + \|\phi(k)\| \\ &\leq 2\|a\|\|\phi(1_A)\|. \end{aligned}$$

□

As it turns out, 2 is the best constant.

Example. Let \mathbb{T} be the unit circle in \mathbb{C} , and $C(\mathbb{T})$ be the continuous functions on z . Let z be the coordinate function, and let $S \subseteq C(\mathbb{T})$ be the subspace spanned by $1, z, \bar{z}$. Defining

$$\phi(a + bz + c\bar{z}) = \begin{pmatrix} a & 2b \\ 2c & a \end{pmatrix},$$

An element of S is positive if and only if $c = \bar{b}$ and $a \geq 2|b|$, and an element of $\text{Mat}_2(\mathbb{C})$ is positive if and only if its diagonal entries and determinant are nonnegative real numbers. Thus, it is the case that ϕ is a positive map, but also

$$\begin{aligned} 2\|\phi(1)\| &= 2 \\ &= \|\phi(z)\| \\ &\leq \|\phi\|, \end{aligned}$$

meaning $\|\phi\| = 2\|\phi(1)\|$.

We are interested in seeing when unital, positive maps are contractive.

Lemma: Let A be a C^* -algebra, and let p_i be positive elements of A such that

$$\sum_{i=1}^n p_i \leq 1.$$

If λ_i are scalars with $|\lambda_i| \leq 1$, then

$$\left\| \sum_{i=1}^n \lambda_i p_i \right\| \leq 1.$$

Proof. Note that

$$\begin{pmatrix} \sum_{i=1}^n \lambda_i p_i & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} = \begin{pmatrix} p_1^{1/2} & \cdots & p_n^{1/2} \\ 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \text{diag}(\lambda_1, \dots, \lambda_n) \begin{pmatrix} p_1^{1/2} & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ p_n^{1/2} & 0 & \cdots & 0 \end{pmatrix}.$$

The norm on the matrix on the left is $\left\| \sum_{i=1}^n \lambda_i p_i \right\|$, while the three matrices on the right have norm less than 1, using the fact that $\|a^*a\| = \|a\|^2$. \square

Theorem: Let B be a C^* -algebra, X a compact Hausdorff space, and $C(X)$ the continuous functions on X . Let $\phi: C(X) \rightarrow B$ be a positive map. Then, $\|\phi\| = \|\phi(1)\|$.

Proof. We may assume $\phi(1) \leq 1$. Let $f \in C(X)$ with $\|f\| \leq 1$, and let $\varepsilon > 0$. Now, we may choose a finite open cover $\{U_i\}_{i=1}^n$ of X such that $|f(x) - f(x_i)| < \varepsilon$ for all $x \in U_i$, and let $\{p_i\}_{i=1}^n$ be a partition of unity subordinate to the cover. That is, $\{p_i\}_{i=1}^n$ are nonnegative continuous functions satisfying $\sum_{i=1}^n p_i = 1$ and $p_i(x) = 0$ for $x \notin U_i$.

Set $\lambda_i = f(x_i)$, and note that if $p_i(x) \neq 0$ for some i , then $x \in U_i$ and $|f(x) - \lambda_i| < \varepsilon$. Hence, for any x , we have

$$\begin{aligned} \left| f(x) - \sum_{i=1}^n \lambda_i p_i(x) \right| &= \left| \sum_{i=1}^n (f(x) - \lambda_i) p_i(x) \right| \\ &\leq \sum_{i=1}^n |f(x) - \lambda_i| p_i(x) \\ &\leq \varepsilon \sum_{i=1}^n p_i(x) = \varepsilon. \end{aligned}$$

$$\begin{aligned}
&< \sum_{i=1}^n \varepsilon p_i(x) \\
&= \varepsilon.
\end{aligned}$$

By above, we know that $\left\| \sum_{i=1}^n \lambda_i p_i \right\| \leq 1$, we have

$$\begin{aligned}
\|\phi(f)\| &\leq \left\| \phi\left(f - \sum_{i=1}^n \lambda_i p_i\right) \right\| + \left\| \sum_{i=1}^n \phi(p_i) \right\| \\
&< 1 + \varepsilon \|\phi\|.
\end{aligned}$$

Since ε was arbitrary, we have $\|\phi\| \leq 1$. □

Lemma (Riesz–Fejér Theorem): Let $\tau(e^{i\theta}) = \sum_{n=-N}^N a_n e^{in\theta}$ be a strictly positive function on \mathbb{T} . Then, there is a polynomial $p(z) = \sum_{n=0}^N p_n z^n$ such that

$$\tau(e^{i\theta}) = \left| p(e^{i\theta}) \right|^2.$$

Proof. Note that τ is real-valued, so $a_{-n} = \overline{a_n}$, and a_0 is real. Assuming $a_{-N} \neq 0$, we take $g(z) = \sum_{n=-N}^N a_n z^{n+N}$, so that g is a polynomial of degree $2N$, $g(0) \neq 0$.

We have $g(e^{i\theta}) = \tau(e^{i\theta}) e^{iN\theta} \neq 0$, and that $\overline{g(1/\bar{z})} = z^{-2N} g(z)$.

We write the $2N$ zeros of g as $z_1, \dots, z_N, 1/\bar{z}_1, \dots, 1/\bar{z}_N$.

Set $q(z) = (z - z_1) \cdots (z - z_N)$ and $h(z) = (z - 1/\bar{z}_1) \cdots (z - 1/\bar{z}_N)$. We have that

$$g(z) = a_N q(z) h(z),$$

where

$$\overline{h(z)} = \frac{(-1)^N \bar{z}^N q(1/\bar{z})}{z_1 \cdots z_N}.$$

Thus, we have

$$\begin{aligned}
\tau(e^{i\theta}) &= e^{-iN\theta} g(e^{i\theta}) \\
&= \left| g(e^{i\theta}) \right| \\
&= \left| a_N q(e^{i\theta}) \overline{h(e^{i\theta})} \right| \\
&= \frac{a_N}{z_1 \cdots z_N} \left| q(e^{i\theta}) \right|^2.
\end{aligned}$$

□

Theorem: Let T be an operator on \mathcal{H} with $\|T\| \leq 1$, and let $S \subseteq C(\mathbb{T})$ be the operator system defined by

$$S = \left\{ p(e^{i\theta}) + \overline{q(e^{i\theta})} \mid p, q \text{ are polynomials} \right\}.$$

Then, $\phi: S \rightarrow \mathbb{B}(\mathcal{H})$, given by $\phi(p + \bar{q}) = p(T) + q(T)^*$ is positive.

Proof. It is enough to prove that $\phi(\tau)$ is positive for every *strictly* positive τ .

Let $\tau(e^{i\theta})$ be strictly positive in S , meaning $\tau(e^{i\theta}) = \sum_{\ell,k=0}^n \alpha_\ell \overline{\alpha_k} e^{i(\ell-k)\theta}$. We must prove that

$$\phi(\tau) = \sum_{\ell,k=0}^n \alpha_\ell \overline{\alpha_k} T(\ell-k),$$

where

$$T(j) = \begin{cases} T^j & j \geq 0 \\ (T^*)^{-j} & j < 0. \end{cases}$$

Fix $x \in \mathcal{H}$. Note that

$$\langle \phi(\tau)(x), x \rangle = \left\langle \begin{pmatrix} I & T^* & \cdots & (T^*)^n \\ T & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & T^* \\ T^n & \cdots & T & I \end{pmatrix} \begin{pmatrix} \overline{\alpha_1} x \\ \overline{\alpha_2} x \\ \vdots \\ \overline{\alpha_n} x \end{pmatrix}, \begin{pmatrix} \overline{\alpha_1} x \\ \overline{\alpha_2} x \\ \vdots \\ \overline{\alpha_n} x \end{pmatrix} \right\rangle, \quad (*)$$

where our matrix operator acts on $\mathcal{H}^{(n)}$. Thus, we only need to show that this matrix operator is positive.

To that end, define the $n \times n$ matrix

$$R = \begin{pmatrix} 0 & \cdots & \cdots & \cdots & 0 \\ T & \ddots & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & T & 0 \end{pmatrix},$$

and note that $R^{n+1} = 0$, with $\|R\|_{\text{op}} \leq 1$ (as T is a contraction).

We let I denote the identity operator on $\mathcal{H}^{(n)}$. The matrix operator $(*)$ can be written as

$$I + R + R^2 + \cdots + R^n + R^* + \cdots + (R^*)^n = (I - R)^{-1} + (I - R^*)^{-1} - I,$$

where we used the fact that $R^{n+1} = 0$ in the geometric series for $(I - R)^{-1}$ and $(I - R^*)^{-1}$. To see that this operator is positive, we let $h \in \mathcal{H}^{(n)}$, and let $h = (I - R)y$ for some $y \in \mathcal{H}^{(n)}$. Then,

$$\begin{aligned} \left\langle \left((I - R)^{-1} + (I - R^*)^{-1} - I \right) h, h \right\rangle &= \langle y, (I - R)y \rangle + \langle (I - R^*)(y), y \rangle - \langle (I - R)(y), (I - R)(y) \rangle \\ &= \|y\|^2 - \|R(y)\|^2 \\ &\geq 0, \end{aligned}$$

since R is a contraction. □

Now, we may prove von Neumann's inequality in a different way.

Theorem (von Neumann's Inequality): Let T be an operator on a Hilbert space with $\|T\|_{\text{op}} \leq 1$. Then, for any polynomial p , we have

$$\|p(T)\|_{\text{op}} \leq \|p\|,$$

where $\|p\| = \sup_{\theta} |p(e^{i\theta})|$.

Proof. The operator system defined by

$$S = \left\{ p(e^{i\theta}) + \overline{q(e^{i\theta})} \mid p, q \text{ polynomials} \right\}$$

is a $*$ -algebra that separates points, so by the Stone–Weierstrass theorem, S is dense in $C(\mathbb{T})$. We know that ϕ is bounded, so it extends $C(\mathbb{T})$. The extension to $\bar{S} = C(\mathbb{T})$ is also positive, so ϕ is contractive. \square

Note that if $A(\mathbb{D})$ denotes the functions analytic on \mathbb{D} and continuous on $\bar{\mathbb{D}}$, we know that by the maximum modulus principle that the supremum of any function in $A(\mathbb{D})$ occurs on \mathbb{T} . We may thus consider $A(\mathbb{D})$ as a closed subalgebra of $C(\mathbb{T})$.

Furthermore, polynomials are dense in $A(\mathbb{D})$. Thus, the homomorphism $p \mapsto p(T)$ extends to a homomorphism $f \mapsto f(T)$ that satisfies $\|f(T)\|_{\text{op}} \leq \|f\|$ for all $f \in A(\mathbb{D})$.

Another consequence is that if a is an element of some unital C^* -algebra A with $\|a\| \leq 1$, then there is a unital, positive map $\phi: C(\mathbb{T}) \rightarrow A$ such that $\phi(p) = p(a)$.

Corollary: Let B and C be unital C^* -algebras. Let A be a unital subalgebra of B , and let $S = A + A^*$ be an operator space. If $\phi: S \rightarrow C$ is positive, then $\|\phi(a)\| \leq \|\phi(1)\| \|a\|$.

Proof. Let $a \in A$ with $\|a\| \leq 1$. We may extend ϕ to a positive map on \bar{S} . There is also a positive map $\psi: C(\mathbb{T}) \rightarrow B$ with $\psi(p) = p(a)$. Since A is an algebra, we must have $\text{Ran}(\psi) \subseteq \bar{S}$.

The composition of positive maps is positive, so we have

$$\begin{aligned} \|\phi(a)\| &= \left\| \phi \circ \psi(e^{i\theta}) \right\| \\ &\leq \|\phi \circ \psi(1)\| \|e^{i\theta}\| \\ &= \|\phi(1)\|. \end{aligned}$$

\square

If $\phi(1) = 1$, then ϕ is a contraction on A , though ϕ may not be a contraction on all of S .

Corollary: Let A and B be unital C^* -algebras with $\phi: A \rightarrow B$ a positive map. Then, $\|\phi\|_{\text{op}} = \|\phi(1)\|$.

Lemma: Let A be a C^* -algebra, $S \subseteq A$ an operator system, and $f: S \rightarrow \mathbb{C}$ a linear functional with $f(1) = 1 = \|f\|$. If a is a normal element of A , and $a \in S$, then $f(a) \in \overline{\text{conv}}(\sigma(a))$.

Proof. Suppose not.

The convex hull of a compact set is the intersection of all closed disks containing the set. Then, there exists λ and $r > 0$ such that $|f(a) - \lambda| > r$, where

$$\sigma(a) \subseteq \{z \mid |z - \lambda| \leq r\}.$$

Then, $\sigma(a - \lambda 1) \subseteq \{z \mid |z| \leq r\}$. Since norm and spectral radius agree for normal elements, we have $\|a - \lambda 1\| \leq r$, while $|f(a - \lambda 1)| > r$. This contradicts the fact that $\|f\| \leq 1$. \square

Proposition: Let S be an operator system, B a unital C^* -algebra, and let $\phi: S \rightarrow B$ be a unital contraction. Then, ϕ is positive.

Proof. Since we can represent B on $\mathcal{B}(\mathcal{H})$, we assume $B = \mathcal{B}(\mathcal{H})$ for some Hilbert space \mathcal{H} . Fix $x \in \mathcal{H}$ with $\|x\| = 1$.

Setting $f(a) = \langle \phi(a)x, x \rangle$, we have $f(1) = 1$ and $\|f\| \leq \|\phi\|$. If a is positive, then $f(a)$ is positive by the previous lemma, so since x was arbitrary, $\phi(a)$ is also positive. \square

Proposition: Let A be a unital C^* -algebra, and let M be a unital subspace of A . If B is a unital C^* -algebra, and $\phi: M \rightarrow B$ is a unital contraction, then the map $\tilde{\phi}: M + M^* \rightarrow B$, given by

$$\tilde{\phi}(a + b^*) = \phi(a) + \phi(b)^*$$

is well-defined and the unique positive extension of ϕ to $M + M^*$.

Proof. To prove that $\tilde{\phi}$ is well-defined, it is enough to prove that if a and a^* belong to M , then $\phi(a)^* = \phi(a^*)$. Set

$$S_1 = \{a \mid a \in M \text{ and } a^* \in M\}.$$

Then, S_1 is an operator system, and ϕ is a unital, contractive map on S_1 , hence positive by the previous proposition. Since ϕ is positive, ϕ is self-adjoint, so $\phi(a^*) = \phi(a)^*$, meaning $\tilde{\phi}$ is well-defined.

To see that $\tilde{\phi}$ is positive, we may assume $B = \mathbb{B}(\mathcal{H})$. Fix $x \in S_{\mathcal{H}}$, and set $\tilde{\rho}(a) = \langle \tilde{\phi}(a)(x), x \rangle$. We will show that $\tilde{\rho}$ is positive.

Let $\rho: M \rightarrow \mathbb{C}$ be defined by $\rho(a) = \langle \phi(a)(x), x \rangle$. Then, $\|\rho\| = 1$, and so by the Hahn–Banach theorem, ρ extends to $\rho_1: M + M^* \rightarrow \mathbb{C}$ with $\|\rho_1\| = 1$. Since ρ_1 is positive, $\rho_1(a + b^*) = \rho(a) + \overline{\rho(b)} = \tilde{\rho}(a + b^*)$. Thus $\tilde{\rho}$ is positive. \square

Completely Positive Maps

Definition. If A is a C^* algebra and $M \subseteq A$ is a linear subspace, then we call M an operator space.

We may regard $\text{Mat}_n(M)$ as a subspace of $\text{Mat}_n(A)$, with the norm structure inherited from the unique norm structure on $\text{Mat}_n(A)$. The primary distinguishing feature of an operator space is the fact that $\text{Mat}_n(M)$ has a unique norm for all $n \geq 1$.

Similarly, if $S \subseteq A$ is an operator system, then we endow $\text{Mat}_n(S)$ with the norm and order it inherits from $\text{Mat}_n(A)$.

Definition. If a matrix $S \in \text{Mat}_n(\mathbb{C})$ is positive definite and Hermitian, then S is positive.

Proof. If S is Hermitian, then we know that all the eigenvalues of S are real and that S is diagonalizable with orthonormal vectors $\{v_1, \dots, v_n\}$. Therefore, if

$$\langle S(x), x \rangle \geq 0$$

for all $x \in \mathbb{C}^n$, then so too does this hold for v_j and corresponding λ_j . Thus, $\lambda_j \geq 0$ for all j , so S is positive. \square

Lemma (Ordering of $\text{Mat}_n(\mathbb{B}(\mathcal{H}))$): We have that $(T_{ij})_{ij} \in \text{Mat}_n(\mathbb{B}(\mathcal{H}))_+$ if and only if, for all $x_1, \dots, x_n \in \mathcal{H}$, we have $(\langle T_{ij}(x_j), x_i \rangle)_{ij} \in \text{Mat}_n(\mathbb{C})_+$.

Definition. If B is a C^* -algebra, and $\phi: S \rightarrow B$ is a linear map, then $\phi_n: \text{Mat}_n(S) \rightarrow \text{Mat}_n(B)$ is defined by $\phi_n((a_{ij})_{ij}) = (\phi(a_{ij}))_{ij}$. We call ϕ n -positive if ϕ_n is positive, and ϕ is called completely positive if it is n -positive for all n .

We call ϕ completely bounded if $\sup_n \|\phi_n\|$ is finite. We set

$$\|\phi\|_{cb} = \sup_n \|\phi_n\|.$$

We say ϕ is completely isometric or completely contractive if each ϕ_n is isometric and that $\|\phi\|_{cb} \leq 1$ respectively.

We investigate some of the properties of classes of completely positive maps such that we may prove when they are automatically completely positive.

Lemma: Let A be a C^* -algebra, and let $a, b \in A$. Then, the following hold.

(i) We have $\|a\| \leq 1$ if and only if

$$\begin{pmatrix} 1 & a \\ a^* & 1 \end{pmatrix}$$

is positive in $\text{Mat}_2(A)$.

(ii) We have

$$\begin{pmatrix} 1 & a \\ a^* & b \end{pmatrix}$$

is positive in $\text{Mat}_2(A)$ if and only if $a^*a \leq b$.

Proof. Let A be represented by $\pi: A \rightarrow \mathcal{B}(\mathcal{H})$, and set $T = \pi(a)$. If $\|T\| \leq 1$, then for any $x, y \in \mathcal{H}$, we have

$$\begin{aligned} \left\langle \begin{pmatrix} I & T \\ T^* & I \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}, \begin{pmatrix} x \\ y \end{pmatrix} \right\rangle &= \langle x, x \rangle + \langle T(y), x \rangle + \langle x, T(y) \rangle + \langle y, y \rangle \\ &\geq \|x\|^2 - 2\|T\|_{\text{op}}\|y\|\|x\| + \|y\|^2 \\ &\geq 0. \end{aligned}$$

Conversely, if $\|T\|_{\text{op}} > 1$, then there exist unit vectors x and y such that $\langle T(y), x \rangle < -1$, and the above inner product is negative.

□

Exercise (Exercise 3.2): Let P, Q, A be operators on a Hilbert space \mathcal{H} , with P, Q positive.

(i) Show that

$$\begin{pmatrix} P & A \\ A^* & Q \end{pmatrix} \geq 0$$

if and only if

$$|\langle Ax, y \rangle|^2 \leq \langle Py, y \rangle \langle Qx, x \rangle.$$

(ii) Show that

$$\begin{pmatrix} 1 & A \\ A^* & B \end{pmatrix} \geq 0$$

if and only if $B \geq A^*A$.

(iii) Show that if

$$\begin{pmatrix} P & A \\ A^* & Q \end{pmatrix} \geq 0,$$

then for any $x \in \mathcal{H}$, we have

$$\begin{aligned} 0 &\leq \langle (P + A + A^* + Q)x, x \rangle \\ &\leq \left(\sqrt{\langle Px, x \rangle} + \sqrt{\langle Qx, x \rangle} \right)^2, \end{aligned}$$

hence

$$\|P + AA^* + Q\| \leq \left(\|P\|^{1/2} + \|Q\|^{1/2} \right)^2.$$

(iv) Show that if

$$\begin{pmatrix} P & A \\ A^* & P \end{pmatrix} \geq 0,$$

then $A^*A \leq \|P\|P$, implying $\|A\| \leq \|P\|$.

Solution:

(i) We see that

$$\begin{pmatrix} P & A \\ A^* & Q \end{pmatrix} \geq 0$$

if and only if, for any $x, y \in \mathcal{H}$, we have

$$\begin{pmatrix} \langle Px, x \rangle & \langle Ay, x \rangle \\ \langle A^*x, y \rangle & \langle Qy, y \rangle \end{pmatrix} \geq 0.$$

Thus, we have

$$\det \begin{pmatrix} \langle Px, x \rangle & \langle Ay, x \rangle \\ \langle A^*x, y \rangle & \langle Qy, y \rangle \end{pmatrix} = \langle Px, x \rangle \langle Qy, y \rangle - |\langle Ay, x \rangle|^2 \geq 0,$$

so that

$$|\langle Ay, x \rangle|^2 \leq \langle Px, x \rangle \langle Qy, y \rangle.$$

Suppose that

$$|\langle Ay, x \rangle|^2 \leq \langle Px, x \rangle \langle Qy, y \rangle.$$

Now, for any $x, y \in \mathcal{H}$, we have

$$\begin{aligned} \left\langle \begin{pmatrix} P & A \\ A^* & Q \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}, \begin{pmatrix} x \\ y \end{pmatrix} \right\rangle &= \langle Px, x \rangle + \langle Ay, x \rangle + \langle A^*x, y \rangle + \langle Qy, y \rangle \\ &= \langle Px, x \rangle + 2 \operatorname{Re}(\langle Ay, x \rangle) + \langle Qy, y \rangle \\ &\geq \langle Px, x \rangle - 2|\langle Ay, x \rangle| + \langle Qy, y \rangle \\ &\geq \langle Px, x \rangle - 2\langle Px, x \rangle^{1/2} \langle Qy, y \rangle^{1/2} + \langle Qy, y \rangle \\ &= \left(\langle Px, x \rangle^{1/2} - \langle Qy, y \rangle^{1/2} \right)^2 \\ &\geq 0. \end{aligned}$$

(ii) We begin by assuming that $B \geq A^*A$. Since $B \geq A^*A$, we have

$$\langle (B - A^*A)(y), y \rangle \geq 0,$$

so that

$$\langle By, y \rangle \geq \|Ay\|^2.$$

Thus, in the 2×2 case, we have, for any $\begin{pmatrix} x \\ y \end{pmatrix} \in \mathcal{H}^{(2)}$,

$$\begin{aligned} \left\langle \begin{pmatrix} 1 & A \\ A^* & B \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}, \begin{pmatrix} x \\ y \end{pmatrix} \right\rangle &= \langle x, x \rangle + \langle Ay, x \rangle + \langle A^*x, y \rangle + \langle By, y \rangle \\ &\geq \langle x, x \rangle + \langle Ay, x \rangle + \langle A^*x, y \rangle + \langle Ay, Ay \rangle \\ &= \langle x, x \rangle + \langle Ay, Ay \rangle + 2 \operatorname{Re}(\langle Ay, x \rangle) \\ &\geq \langle x, x \rangle + \langle Ay, Ay \rangle - 2\|Ay\|\|x\| \\ &= \|x\|^2 + \|Ay\|^2 - 2\|Ay\|\|x\| \end{aligned}$$

$$\geq 0.$$

Thus, the matrix is positive.

For the converse direction, we suppose $B \not\geq A^*A$. Then, there is some $y \in \mathcal{H}$ such that $\langle (B - A^*A)(y), y \rangle < 0$. This gives $\langle By, y \rangle < \|Ay\|^2$. We may select y such that $\|Ay\|^2 = 1$. Setting $x = -Ay$, we have

$$\begin{aligned} \left\langle \begin{pmatrix} 1 & A \\ A^* & B \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}, \begin{pmatrix} x \\ y \end{pmatrix} \right\rangle &= \langle x, x \rangle + \langle Ay, x \rangle + \langle A^*x, y \rangle + \langle By, y \rangle \\ &= \langle x, x \rangle + \langle Ay, x \rangle + \langle x, Ay \rangle + \langle By, y \rangle \\ &= \langle -Ay, -Ay \rangle + \langle Ay, -Ay \rangle + \langle -Ay, Ay \rangle + \langle By, y \rangle \\ &= \|Ay\|^2 - 2\|Ay\|^2 + \langle By, y \rangle \\ &= -1 + \langle By, y \rangle \\ &< -1 + \|Ay\|^2 \\ &= 0. \end{aligned}$$

Thus, the matrix is negative.

(iii) We apply the result in (i) to the vector $\begin{pmatrix} x \\ x \end{pmatrix}$. This gives

$$\begin{aligned} \left\langle \begin{pmatrix} P & A \\ A^* & Q \end{pmatrix} \begin{pmatrix} x \\ x \end{pmatrix}, \begin{pmatrix} x \\ x \end{pmatrix} \right\rangle &= \langle Px, x \rangle + \langle Ax, x \rangle + \langle A^*x, x \rangle + \langle Qx, x \rangle \\ &= \langle Px, x \rangle + 2\operatorname{Re}(\langle Ax, x \rangle) + \langle Qx, x \rangle \\ &\leq \langle Px, x \rangle + 2|\langle Ax, x \rangle| + \langle Qx, x \rangle \\ &\leq \langle Px, x \rangle + 2\langle Px, x \rangle^{1/2} \langle Qx, x \rangle^{1/2} + \langle Qx, x \rangle \\ &= \left(\langle Px, x \rangle^{1/2} + \langle Qx, x \rangle^{1/2} \right)^2. \end{aligned}$$

(iv) Setting $Q = P$ in the result from (i), we have

$$|\langle Ay, x \rangle|^2 \leq \langle Px, x \rangle \langle Py, y \rangle,$$

which holds for all $x, y \in \mathcal{H}$. In particular, setting $x = Ay$, we have

$$\begin{aligned} |\langle Ay, Ay \rangle| &\leq \langle PAy, Ay \rangle \langle Py, y \rangle \\ &\leq \|PAy\| \|Ay\| \langle Py, y \rangle \\ &\leq \|P\| \|Ay\|^2 \langle Py, y \rangle. \end{aligned}$$

This gives

$$\begin{aligned} \|Ay\|^4 &\leq \|P\| \|Ay\|^2 \langle Py, y \rangle \\ \|Ay\|^2 &\leq \|P\| \langle Py, y \rangle \\ \langle A^*Ay, y \rangle &\leq \|P\| \langle Py, y \rangle, \end{aligned}$$

or that $A^*A \leq \|P\|P$.

Proposition: Let S be an operator system, B a unital C^* -algebra, and $\phi: S \rightarrow B$ a unital 2-positive map. Then, ϕ is contractive.

Proof. Let $a \in S$ with $\|a\| \leq 1$. Then,

$$\phi_2 \begin{pmatrix} 1 & a \\ a^* & 1 \end{pmatrix} = \begin{pmatrix} 1 & \phi(a) \\ \phi(a)^* & 1 \end{pmatrix}$$

is positive, hence $\|\phi(a)\| \leq 1$. □

Proposition (Cauchy–Schwarz for 2-positive Maps): Let A, B be unital C^* -algebras, and let $\phi: A \rightarrow B$ be a unital 2-positive map. Then,

$$\phi(a)^* \phi(a) \leq \phi(a^*a)$$

for all $a \in A$.

Proof. We have that

$$\begin{pmatrix} 1 & a \\ 0 & 0 \end{pmatrix}^* \begin{pmatrix} 1 & a \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & \phi(a) \\ \phi(a)^* & \phi(a^*a) \end{pmatrix} \geq 0,$$

meaning that $\phi(a)^* \phi(a) \leq \phi(a^*a)$ by above. \square

Proposition: Let A and B be unital C^* -algebras, and let M be a unital subspace of M , with $S = M + M^*$. If $\phi: M \rightarrow B$ is unital and 2-contractive, then $\tilde{\phi}: S \rightarrow B$ given by $\tilde{\phi}(a + b^*) = \phi(a) + \phi(b)^*$ is 2-positive and contractive.

Proof. Since ϕ is contractive, we know from above that $\tilde{\phi}$ is well-defined. Furthermore, note that

$$\text{Mat}_2(S) = \text{Mat}_2(M) + \text{Mat}_2(M)^*,$$

and

$$(\tilde{\phi})_2 = (\tilde{\phi}_2).$$

Now, since ϕ_2 is contractive, we have that $\tilde{\phi}_2$ is positive, so $\tilde{\phi}$ is contractive. \square

Proposition: Let A and B be unital C^* -algebras, let M be a unital subspace, and let $S = M + M^*$. If $\phi: M \rightarrow B$ is unital and completely contractive, then $\tilde{\phi}: S \rightarrow B$ is completely positive and completely contractive.

Proof. Since ϕ_n is unital and contractive, $\tilde{\phi}_n$ is positive. Additionally, since $(\tilde{\phi}_n)_2$ is positive, $\tilde{\phi}_n$ is contractive. \square

Note that since $\text{Mat}_2(\text{Mat}_n(A)) \cong \text{Mat}_{2n}(A)$ are $*$ -isomorphic, the norm on $\text{Mat}_2(\text{Mat}_n(A))$ is equal to the norm on $\text{Mat}_{2n}(A)$.

Now, we may see some examples that belong to these categories.

Example. If A and B are C^* -algebras, and $\pi: A \rightarrow B$ is a $*$ -homomorphism, then π is completely positive and completely contractive, since each $\pi_n: \text{Mat}_n(A) \rightarrow \text{Mat}_n(B)$ is a $*$ -homomorphism, and $*$ -homomorphisms are both positive and contractive.

Example. Fixing $x, y \in A$, we may define $\phi: A \rightarrow A$ by $\phi(a) = xay$. Note that if $(a_{ij})_{ij} \in \text{Mat}_n(A)$, then

$$\begin{aligned} \left\| \phi_n \left((a_{ij})_{ij} \right) \right\| &= \left\| (xa_{ij}y)_{ij} \right\| \\ &= \left\| (xI_n) \begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{pmatrix} (yI_n) \right\| \\ &\leq \|x\| \left\| (a_{ij})_{ij} \right\| \|y\|. \end{aligned}$$

This means ϕ is completely bounded with $\|\phi\|_{cb} \leq \|x\| \|y\|$. Similarly, if $x = y^*$, then ϕ_n is positive.

This gives us the archetype of a completely bounded map. If \mathcal{H}_1 and \mathcal{H}_2 are Hilbert spaces, and $v_i: \mathcal{H}_1 \rightarrow \mathcal{H}_2$ are bounded operators for $i = 1, 2$, then if $\pi: A \rightarrow \mathcal{B}(\mathcal{H}_2)$ is a $*$ -homomorphism, we may define $\phi: A \rightarrow \mathcal{B}(\mathcal{H}_1)$ by $\phi(a) = v_2^* \pi(a) v_1$. This function ϕ is completely bounded with $\|\phi\|_{cb} \leq \|v_1\| \|v_2\|$.

In fact, we will show that *every* completely bounded map is of this form.

Proposition: Let $S \subseteq A$ be an operator system, B a C^* -algebra, and $\phi: S \rightarrow B$ completely positive. Then, ϕ is completely bounded, and $\|\phi(1)\| = \|\phi\| = \|\phi\|_{cb}$.

Proof. We have $\|\phi(1)\| \leq \|\phi\| \leq \|\phi\|_{cb}$, so it is sufficient to show that $\|\phi\|_{cb} \leq \|\phi(1)\|$. Let $A = (a_{ij})_{ij}$ be in $\text{Mat}_n(S)$ with $\|A\| \leq 1$, and let I_n be the unit of $\text{Mat}_n(A)$. Then, since

$$T = \begin{pmatrix} I_n & A \\ A^* & I_n \end{pmatrix}$$

is positive, the map

$$\phi_{2n} \left(\begin{pmatrix} I_n & A \\ A^* & I_n \end{pmatrix} \right) = \begin{pmatrix} \phi_n(I_n) & \phi_n(A) \\ \phi_n(A)^* & \phi_n(I_n) \end{pmatrix}$$

is positive, so $\|\phi_n(A)\| \leq \|\phi_n(I_n)\| = \|\phi(1)\|$. □

Schur Products and Tensor Products

We will apply the previous results on positive and completely positive maps on the Schur product.

Definition. If $A = (a_{ij})_{ij}$ and $B = (b_{ij})_{ij}$, then the Schur product is defined by

$$A * B = (a_{ij} b_{ij})_{ij}.$$

Note that for a fixed A , we get a linear map

$$S_A(B) = A * B.$$

To study the Schur product, we review some results on tensor products.

Let $A \in \text{Mat}_n(\mathbb{C})$ and $B \in \text{Mat}_m(\mathbb{C})$. Then, $A \otimes B$ is the linear transformation on $\mathbb{C}^n \otimes \mathbb{C}^m = \mathbb{C}^{nm}$, defined by $A \otimes B(x \otimes y) = Ax \otimes By$ with the unique linear extension provided by the tensor product.

Note that we have $\|A \otimes B\| = \|A\| \|B\|$, which is shown by writing $A \otimes B = (A \otimes I)(I \otimes B)$.

Now, letting $\{e_1, \dots, e_n\}$ and $\{f_1, \dots, f_m\}$ be our canonical orthonormal bases for \mathbb{C}^n and \mathbb{C}^m respectively, we may order our basis as $e_1 \otimes f_1$, then $e_2 \otimes f_1$, etc., yielding the block matrices for $A \otimes B$ is

$$\begin{pmatrix} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{n1}B & \cdots & a_{nn}B \end{pmatrix}.$$

This matrix is known as the Kronecker product of A and B . Now, similarly, we may order our basis by $e_i \otimes f_1$, then $e_i \otimes f_2$, etc., yielding a different block matrix of the form

$$\begin{pmatrix} b_{11}A & \cdots & b_{1m}A \\ \vdots & \ddots & \vdots \\ b_{m1}A & \cdots & b_{mm}A \end{pmatrix},$$

which is the Kronecker product of B and A .

Now, since both of these matrices represent the same linear transformation, they are unitarily equivalent, given by the permutation matrix that reorders the basis vectors. One obtains the (k, ℓ) entry of the (i, j) block of $b_{ij}A$ by taking the (i, j) entry of the (k, ℓ) block $a_{k, \ell}B$. We will call this the *canonical shuffle*.

Now, we let A and B be elements of $\text{Mat}_n(\mathbb{C})$, and define $V: \mathbb{C}^n \rightarrow \mathbb{C}^n \otimes \mathbb{C}^n$ to be the isometry given by $V(e_i) = e_i \otimes e_i$. We will show that $V^*(A \otimes B)V = A * B$. Note that

$$\begin{aligned} \langle V^*(A \otimes B)V e_j, e_i \rangle &= \langle (A \otimes B)(e_j \otimes e_j), e_i \otimes e_i \rangle \\ &= \langle A e_j, e_i \rangle \langle B e_j, e_i \rangle \\ &= a_{ij} b_{ij} \\ &= \langle A * B e_j, e_i \rangle. \end{aligned}$$

Thus,

$$\begin{aligned} \|S_A(B)\| &\leq \|V^*(A \otimes B)V\| \\ &\leq \|A\| \|B\|, \end{aligned}$$

so that

$$\|S_A\| \leq \|A\|.$$

Now, if $(B_{ij})_{ij} \in \text{Mat}_k(\text{Mat}_n(\mathbb{C}))$, then

$$\begin{aligned} (S_A)\left((B_{ij})_{ij}\right) &= (V^*(A \otimes B_{ij})V)_{ij} \\ &= \begin{pmatrix} V^* & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & V^* \end{pmatrix} A \otimes \begin{pmatrix} B_{11} & \cdots & B_{1n} \\ \vdots & \ddots & \vdots \\ B_{n1} & \cdots & B_{nn} \end{pmatrix} \begin{pmatrix} V & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & V \end{pmatrix}, \end{aligned}$$

so that $\|(S_A)_k\| \leq \|A\|$. Thus, $\|S_A\|_{cb} \leq \|A\|$.

However, this isn't a really good estimate. For instance, if A is the matrix consisting of all 1s, then the norm of A is n , while $\|S_A\| = 1$.

We will prove that if A is positive, then S_A is completely positive. Thus, for positive matrices, we are able to obtain $\|S_A\|_{cb}$ by finding

$$\begin{aligned} \|S_A\| &= \|S_A(I)\| \\ &= \|S_A\|_{cb} \\ &= \max\{a_{ii} \mid i = 1, \dots, n\}. \end{aligned}$$

Now, if A is not positive, then obtaining this norm is a bit more difficult. We can decompose $A = (P_1 - P_2) + i(P_3 - P_4)$, and get

$$\|S_A\|_{cb} \leq \|S_{P_1}\|_{cb} + \|S_{P_2}\|_{cb} + \|S_{P_3}\|_{cb} + \|S_{P_4}\|_{cb},$$

but unfortunately this estimate isn't really enough.

Now, we will characterize when the Schur product is completely positive.

Theorem: Let $A = (a_{ij})_{ij} \in \text{Mat}_n(\mathbb{C})$. The following are equivalent:

- (i) A is positive;

(ii) $S_A: \text{Mat}_n(\mathbb{C}) \rightarrow \text{Mat}_n(\mathbb{C})$ is positive;

(iii) $S_A: \text{Mat}_n(\mathbb{C}) \rightarrow \text{Mat}_n(\mathbb{C})$ is completely positive.

Proof. We have that (iii) implies (ii), and (ii) implies (i) by choosing J to be the matrix consisting of 1, which is positive, meaning $S_A(J) = A$. Thus, we must prove that (i) implies (iii).

Note that if A and B are positive, then $A \otimes B$ is positive. This follows from the fact that $A \otimes B = \left(A^{1/2} \otimes B^{1/2}\right)^2$.

Now, if $B \in \text{Mat}_n(\mathbb{C})$ is positive, then

$$\begin{aligned} S_A(B) &= V^*(A \otimes B)V \\ &= \left(\left(A^{1/2} \otimes B^{1/2} \right) V \right)^* \left(\left(A^{1/2} \otimes B^{1/2} \right) V \right) \end{aligned}$$

is positive, meaning (i) implies (ii).

Now, to see that (i) implies (iii), we let $B = (B_{ij})_{ij} \in \text{Mat}_k(\text{Mat}_n(\mathbb{C}))$, and write $B = (X_{ij})_{ij}^* (X_{ij})_{ij}$. We see that

$$\begin{aligned} (S_A)_k(B) &= (V^*(A \otimes B_{ij})V) \\ &= \left(\left(A^{1/2} \otimes X_{ij} \right) V \right)^* \left(\left(A^{1/2} \otimes X_{ij} \right) V \right), \end{aligned}$$

meaning $(S_A)_k$ is positive. □

There is an analogous theory of Schur products in the space $\mathbb{B}(\ell_2)$, where we consider the bounded operators as infinite matrices. If we mandate that $A \in \mathbb{B}(\ell_2)_+$, then we can use a similar line of argumentation to show that S_A is completely positive, but this requires a bit more care as the matrix consisting of all 1s regarded as an operator on ℓ_2 is not a bounded operator.

Now, we can show a pretty useful result, which is that bounded linear functionals are not only positive, but completely positive.

Proposition: Let S be an operator space, and let $f: S \rightarrow \mathbb{C}$ be a bounded linear functional. Then,

$$\|f\|_{\text{cb}} = \|f\|_{\text{op}},$$

and if S is an operator system with f positive, then f is completely positive.

Proof. Let $(a_{ij})_{ij} \in \text{Mat}_n(S)$, and let $x, y \in \mathbb{C}^n$ be unit vectors. Then,

$$\begin{aligned} \left| \left\langle f((a_{ij})_{ij})(x), y \right\rangle \right| &= \left| \sum_{i,j=1}^n f(a_{ij})(x_j) \overline{y_i} \right| \\ &= \left| f \left(\sum_{i,j=1}^n a_{ij} x_j \overline{y_i} \right) \right| \\ &\leq \|f\|_{\text{op}} \left\| \sum_{i,j=1}^n a_{ij} x_j \overline{y_i} \right\|. \end{aligned}$$

Now, all we need to show is that the latter element has norm less than $\|(a_{ij})_{ij}\|$. Note that this sum is the entry on the first row and column of the matrix that represents the product

$$\begin{pmatrix} \overline{y_1} & \cdots & \overline{y_n} \\ 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{pmatrix} \begin{pmatrix} x_1 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ x_n & 0 & \cdots & 0 \end{pmatrix}.$$

The outer two factors have norm 1, since x and y are chosen to be unit vectors.

To show that f is completely positive, we only need to show that

$$\left\langle f_n \left((a_{ij})_{ij} \right) (x), x \right\rangle = f \left(\sum_{i,j=1}^n a_{ij} x_j \overline{x_i} \right)$$

is positive whenever $(a_{ij})_{ij}$ is positive. However, using the above product, we see that the summation is equal to the first row and column entry of a positive matrix, hence positive. \square

Now, we examine the positivity and boundedness of maps with codomain $C(X)$, where X is a compact Hausdorff space.

Note that every element $F = (f_{ij})_{ij}$ of $\text{Mat}_n(C(X))$ can be considered as a continuous matrix-valued function, with multiplication and $*$ -operation as pointwise multiplication and involution of the matrix-valued functions.

To make $\text{Mat}_n(C(X))$ into a C^* -algebra is to set $\|F\| = \sup\{\|F(x)\| \mid x \in X\}$, and by uniqueness of C^* -norms, this is the only way to create a C^* -norm.

Theorem: Let S be an operator space, and let $\phi: S \rightarrow C(X)$ be a bounded linear map. Then, $\|\phi\|_{cb} = \|\phi\|_{op}$. Furthermore, if S is an operator system and ϕ is positive, then ϕ is completely positive.

Proof. Let $x \in X$, and define ϕ^x to be pointwise evaluation — i.e., $\phi^x(a) = \phi(a)(x)$. Then,

$$\begin{aligned} \|\phi_n\| &= \sup\{\|\phi_n^x\| \mid x \in X\} \\ &= \sup\{\|\phi^x\| \mid x \in X\} \\ &= \|\phi\|_{op}. \end{aligned}$$

Similarly, $\phi_n \left((a_{ij})_{ij} \right)$ is positive if and only if $\phi_n^x \left((a_{ij})_{ij} \right)$ is positive for all $x \in X$. \square

Thus, when the codomain C^* -algebra is commutative, boundedness and complete boundedness, as well as positivity and complete positivity, coincide. A commutative domain is enough to show that positive maps are completely positive, but unfortunately a commutative domain is not enough to guarantee that bounded maps are completely bounded.

Lemma: Let $(p_{ij})_{ij}$ be a positive scalar matrix, and let q be a positive element of some C^* -algebra B . Then, $(p_{ij}q)_{ij}$ is positive in $\text{Mat}_n(B)$.

Proof. We write $(p_{ij})_{ij}$ as $(s_{ij})_{ij}^* (s_{ij})_{ij}$, and write $q = n^*n$. This gives

$$\begin{aligned} (p_{ij}q)_{ij} &= (p_{ij})_{ij} \text{diag}(q, \dots, q) \\ &= (s_{ij})_{ij}^* (s_{ij})_{ij} \text{diag}(n^*n, \dots, n^*n) \\ &= (s_{ij})_{ij}^* (s_{ij})_{ij} \text{diag}(n^*, \dots, n^*) \text{diag}(n, \dots, n) \\ &= (s_{ij})_{ij}^* (s_{ij})_{ij} \text{diag}(n, \dots, n)^* \text{diag}(n, \dots, n) \\ &= \text{diag}(n, \dots, n)^* (s_{ij})_{ij}^* (s_{ij})_{ij} \text{diag}(n, \dots, n) \quad \text{diag}(n, \dots, n) \in \text{Mat}_n(B), (s_{ij})_{ij} \in \text{Mat}_n(\mathbb{C}) \\ &= \left((s_{ij})_{ij} \text{diag}(n, \dots, n) \right)^* \left((s_{ij})_{ij} \text{diag}(n, \dots, n) \right). \end{aligned}$$

Thus, $(p_{ij}q)_{ij}$ is positive in $\text{Mat}_n(B)$. \square

Theorem: Let B be a C^* -algebra, and let $\phi: C(X) \rightarrow B$ be a positive map. Then, ϕ is completely positive.

Proof. Let $P(x)$ be positive in $\text{Mat}_n(C(X))$. We prove that $\phi_n(P)$ is positive.

Given $\varepsilon > 0$, we may find a partition of unity $\{u_\ell(x)\}_{\ell=1}^m$ and positive matrices $P_\ell = (p_{ij}^\ell)_{ij}$ such that

$$\left| P - \sum_{\ell=1}^m u_\ell(x) P_\ell \right| < \varepsilon.$$

However, we know that

$$\begin{aligned} \phi_n(u_\ell P_\ell) &= \phi_n\left((u_\ell p_{ij}^\ell)_{ij}\right) \\ &= (\phi(u_\ell) p_{ij}^\ell)_{ij}, \end{aligned}$$

which is positive. Therefore, $\phi_n(P)$ is within $\varepsilon \|\phi_n\| \|P\|$ of a sum of positive elements. Since $\text{Mat}_n(B)_+$ is a closed set, we have that $\phi_n(P)$ is positive. \square

Corollary: Let T be a contractive operator on \mathcal{H} , and let $(p_{ij})_{ij}$ be a $n \times n$ matrix of polynomials. Then,

$$\|(p_{ij}(T))_{ij}\|_{\text{op}} \leq \sup \left\{ \|(p_{ij}(z))_{ij}\| \mid |z| = 1 \right\}.$$

Proof. The map given by $\phi(p + \bar{q}) = p(T) + q(T)^*$ extends to a positive map $\varphi: C(\mathbb{T}) \rightarrow \mathcal{B}(\mathcal{H})$. This map is completely positive as $C(\mathbb{T})$ is a commutative C^* -algebra. Thus, $\|\varphi\|_{\text{cb}} = \|\varphi(1)\| = 1$. Thus,

$$\begin{aligned} \|(p_{ij}(T))_{ij}\| &= \|\phi_n((p_{ij})_{ij})\| \\ &\leq \|(p_{ij}(1))_{ij}\|. \end{aligned}$$

\square

Lemma: Let A be a C^* -algebra. Then, every positive element of $\text{Mat}_n(A)$ is a sum of n positive elements of the form $(a_i^* a_j)_{ij}$, where $\{a_1, \dots, a_n\} \subseteq A$.

Proof. Note that if R is the element of $\text{Mat}_n(A)$ whose k th row is a_1, \dots, a_n and 0 elsewhere, then $R^* R = (a_i^* a_j)_{ij}$, so such an element is positive.

Now, let P be positive, yielding $P = B^* B$. Write $B = R_1 + \dots + R_n$, where R_k is the k th row of B and 0 elsewhere.

Then, since $R_i^* R_j = 0$ whenever $i \neq j$, we have that $P = R_1^* R_1 + \dots + R_n^* R_n$. \square

Thus, it suffices to check that $\phi: A \rightarrow B$ is n -positive by verifying that $(\phi(a_i^* a_j))_{ij}$ is positive for all $a_1, \dots, a_n \in A$.

Theorem: Let B be a C^* -algebra, let $\phi: \text{Mat}_n(\mathbb{C}) \rightarrow B$ be a linear map, and let $\{e_{ij}\}_{i,j=1}^n$ denote the standard matrix units for $\text{Mat}_n(\mathbb{C})$. The following are equivalent:

- (i) ϕ is completely positive;
- (ii) ϕ is n -positive;
- (iii) $(\phi(e_{ij}))_{ij}$ is positive in $\text{Mat}_n(B)$.

Proof. It suffices to show that (iii) implies (i), as (i) implies (ii) and $(e_{ij})_{ij}$ is positive for each i, j , giving (ii) implies (iii).

It is sufficient to assume that $B = \mathbb{B}(\mathcal{H})$. Fix k , and let $x_1, \dots, x_k \in \mathcal{H}$, $B_1, \dots, B_k \in \text{Mat}_n(\mathbb{C})$. It is sufficient to prove that

$$\sum_{i,j}^k \langle \phi(B_i^* B_j) x_j, x_i \rangle \geq 0.$$

Write $B_\ell = \sum_{r,s=1}^n b_{rs,\ell} e_{rs}$, such that

$$B_i^* B_j = \sum_{r,s,t=1}^n \overline{b_{rs,i}} b_{rt,j} e_{st}.$$

Set $y_{t,r} = \sum_{j=1}^k b_{rt,j} x_j$. Then,

$$\begin{aligned} \sum_{i,j=1}^k \langle \phi(B_i^* B_j) x_j, x_i \rangle &= \sum_{r=1}^n \sum_{s,t=1}^n \left\langle \phi(e_{st}) \left(\sum_{i,j=1}^k b_{rs,i} b_{rt,j} x_j \right), x_i \right\rangle \\ &= \sum_{r=1}^n \sum_{s,t} \langle \phi(e_{st}) y_{t,r}, y_{s,r} \rangle. \end{aligned}$$

However, this latter sum is positive, since $(\phi(e_{st}))_{st}$ is positive, so we have expressed our original sum as the sum of n positive quantities. \square

Now, we may obtain some fairly deep results in operator theory via the properties of positive maps.

Definition. If $T \in \mathbb{B}(\mathcal{H})$, we define the numerical radius of T by

$$w(T) = \sup_{x \in \mathcal{B}_{\mathcal{H}}} |\langle Tx, x \rangle|.$$

Exercise: Let S_n be the cyclic forward shift on \mathbb{C}^n . That is, $S_n e_j = e_{j+1 \bmod n}$, where e_0, \dots, e_{n-1} is the canonical basis for \mathbb{C}^n .

- (i) Show that S_n is unitarily equivalent to a diagonal matrix whose entries are the n th roots of unity.
- (ii) Let $T \in \mathbb{B}(\mathcal{H})$. Show that $w(T) = w(T \otimes S_n)$.
- (iii) Let R_n be the $n \times n$ matrix of operators whose subdiagonals are T and 0 elsewhere. Show that $w(R_n) \leq w(T \otimes S_n)$.
- (iv) Show that $\text{Re}(\langle R_n y, y \rangle) \leq 1$ for all $\|y\| = 1$ if and only if $w(R_n) \leq 1$.

Solution:

- (i) By the definition of the cyclic forward shift, defining $A := S_n$, we have $A^n = I_n$, or $A^n - I = 0$. This means that the minimal polynomial for S_n is $m_{S_n}(x) = x^n - 1$, meaning that the n th roots of unity are eigenvalues for S . Since S_n is an operator acting on \mathbb{C}^n , there are at n eigenvalues (with multiplicity) for S_n , meaning that the n th roots of unity are in fact *the* eigenvalues of S_n . Thus, S_n is unitarily equivalent to a diagonal matrix with the n th roots of unity on the diagonal.

- (ii) The operator $T \otimes S_n$ acts on $\mathcal{H} \otimes \mathbb{C}^n$ such that $(T \otimes S_n)(y \otimes v) = Ty \otimes S_n v$. Thus, we have

$$\begin{aligned} w(T \otimes S_n) &= \sup_{y \otimes v \in \mathcal{B}_{\mathcal{H} \otimes \mathbb{C}^n}} |\langle (T \otimes S_n)(y \otimes v), y \otimes v \rangle| \\ &= \sup_{y \otimes v \in \mathcal{B}_{\mathcal{H} \otimes \mathbb{C}^n}} |\langle Ty \otimes S_n v, y \otimes v \rangle| \\ &= \sup_{y \in \mathcal{B}_{\mathcal{H}}} \sup_{v \in \mathcal{B}_{\mathbb{C}^n}} |\langle Ty, y \rangle| |\langle S_n v, v \rangle| \\ &= w(T) w(S_n) \\ &= w(T). \end{aligned}$$

- (iii) We consider the non-cyclic shift S'_n , and note that $w(S'_n) \leq w(S_n)$, as applying the non-cyclic shift will yield zero in the first entry of the vector v . We have that $R_n \cong T \otimes S'_n$, meaning that $w(R_n) \leq w(T)$.
- (iv) If $w(R_n) \leq 1$ for all $\|y\| = 1$, then since $\operatorname{Re}(\langle R_n y, y \rangle) \leq |\langle R_n y, y \rangle| \leq 1$, it is clear that $\operatorname{Re}(\langle R_n y, y \rangle) \leq 1$ for all $\|y\| = 1$.

Now, suppose $\operatorname{Re}(\langle R_n y, y \rangle) \leq 1$ for all $\|y\| = 1$.

Theorem: Let $T \in \mathcal{B}(\mathcal{H})$, let $S \subseteq C(\mathbb{T})$ be the operator system defined by $S = \{p + \bar{q} \mid p, q \text{ polynomials}\}$. The following are equivalent:

- (i) $w(T) \leq 1$;
- (ii) the map $\phi: S \rightarrow \mathcal{B}(\mathcal{H})$, defined by

$$\phi(p + \bar{q}) = p(T) + q(T)^* + \left(p(0) + \overline{q(0)}\right)I$$

is positive.

Proof. We start by showing that (i) implies (ii).

Let R_n be the $n \times n$ operator matrix with subdiagonal entry T and remaining entries 0. Note that $w(R_n) \leq w(T)$.

Now, we see that ϕ is positive so long as the matrix

$$\begin{pmatrix} 2 & T^* & \cdots & (T^*)^n \\ T & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & T^* \\ T^n & \cdots & T & 2 \end{pmatrix} \quad (*)$$

is positive for all n .

Note that $R_n^{n+1} = 0$, so $(*)$ can be written as $(I - R_n)^{-1} + (I - R_n^*)^{-1}$.

Fix $x = (I - R_n)y$, and compute

$$\left\langle \left((I - R_n)^{-1} + (I - R_n^*)^{-1} \right) x, x \right\rangle = 2\|y\|^2 - 2\operatorname{Re}(\langle R_n y, y \rangle).$$

Thus, $(*)$ is positive if and only if $w(R_n) \leq 1$. Since $w(T) \leq 1$ implies $w(R_n) \leq 1$, we have $(*)$ is positive, meaning ϕ is positive.

Conversely, if ϕ is positive, since $\bar{S} = C(\mathbb{T})$, ϕ is completely positive by the fact that if $\phi: C(X) \rightarrow B$ is positive, then ϕ is completely positive.

Note that

$$\begin{pmatrix} 1 & \bar{z} & \cdots & \bar{z}^n \\ z & 1 & \cdots & \ddots \\ \vdots & \ddots & \ddots & \bar{z} \\ z^n & \cdots & z & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & z & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & z^n \end{pmatrix} \begin{pmatrix} 1 & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & \cdots & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & \bar{z} & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & \bar{z}^n \end{pmatrix}$$

is positive in $\operatorname{Mat}_n(C(\mathbb{T}))$, so its image under ϕ_n is also positive. However, since this image is equal to $(*)$, we have that $(*)$ is positive for all n , meaning $w(R_n) \leq 1$.

Let $x \in \mathcal{H}$, $\|x\| = 1$, and $y = \frac{1}{\sqrt{n}}(x \oplus \cdots \oplus x)$ be a unit vector $\mathcal{H} \oplus \cdots \oplus \mathcal{H}$. Then, we have

$$\begin{aligned} 1 &\leq |\langle R_n y, y \rangle| \\ &= \frac{n-1}{n} |\langle T x, x \rangle|, \end{aligned}$$

meaning $w(t) \leq \frac{n}{n-1}$ for all n , meaning $w(T) \leq 1$. □

If $w(T) \leq 1$, we may extend the functional calculus from the circle to the disk algebra, $A(\mathbb{D})$.

Corollary: Let $T \in \mathcal{B}(\mathcal{H})$ with $w(T) \leq 1$. Let $f \in A(\mathbb{D})$ with $f(0) = 0$. Then, $w(f(T)) \leq \|f\|$.

Proof. It is sufficient to assume that f is a polynomial, and $\|f\| \leq 1$. □

Dilations

We saw our first example of a dilation theorem earlier in our first proof of von Neumann's inequality when we showed that if T is contractive, there is some projection P from $\mathcal{K} \supseteq \mathcal{H}$ and some unitary $U \in \mathcal{B}(\mathcal{K})$ such that $T^n = P U^n|_{\mathcal{H}}$.

Now, we will show an incredibly powerful result that characterizes all the completely positive maps, known as Stinespring's dilation theorem.

Theorem (Stinespring's Dilation): Let A be a unital C^* -algebra, and let $\phi: A \rightarrow \mathcal{B}(\mathcal{H})$ be a completely positive map. Then, there exists a Hilbert space \mathcal{K} , a unital $*$ -homomorphism $\pi: \mathcal{B}(\mathcal{K})$, and a bounded operator $V: \mathcal{H} \rightarrow \mathcal{K}$ with $\|\phi(1)\| = \|V\|_{\text{op}}^2$, such that

$$\phi(a) = V^* \pi(a) V$$

for all $a \in A$.

Proof. Consider the algebraic tensor product $A \otimes \mathcal{H}$, and define the symmetric bilinear map $\langle \cdot, \cdot \rangle$ on the space by setting

$$\langle a \otimes x, b \otimes y \rangle = \langle \phi(b^* a) x, y \rangle_{\mathcal{H}},$$

and extending linearly.

Since we have

$$\begin{aligned} \left\langle \sum_{j=1}^n a_j \otimes x_j, \sum_{i=1}^n a_i \otimes x_i \right\rangle &= \left\langle \phi_n \left((a_i^* a_j)_{ij} \right) \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}, \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \right\rangle_{\mathcal{H}^{(n)}} \\ &\geq 0, \end{aligned}$$

and ϕ is completely positive, we have that $\langle a \otimes x, b \otimes y \rangle$ is a positive semidefinite bilinear form.

Since positive semidefinite bilinear forms satisfy the Cauchy-Schwarz inequality, $|\langle u, v \rangle| \leq \langle u, u \rangle \langle v, v \rangle$, we may define the "null set"

$$N := \{u \in A \otimes \mathcal{H} \mid \langle u, u \rangle = 0\}$$

as a subspace of $A \otimes \mathcal{H}$. The induced inner product on $(A \otimes \mathcal{H})/N$ is

$$\langle u + N, v + N \rangle = \langle u, v \rangle.$$

Remark: The construction here is very similar to the GNS construction.

We will let \mathcal{K} be the completion of $(A \otimes \mathcal{H})/N$.

Now, if $a \in A$, define $\pi(a): A \otimes \mathcal{H} \rightarrow A \otimes \mathcal{H}$ by

$$\pi(a) \left(\sum_{i=1}^n a_i \otimes x_i \right) = \sum_{i=1}^n (a a_i) \otimes x_i.$$

We begin by showing that

$$(a_i^* a^* a a_j)_{ij} \leq \|a^* a\| (a_i^* a_j)_{ij},$$

where the inequality is in $\text{Mat}_n(A)_+$. This follows from the fact that

$$\begin{aligned} (a_i^* a^* a a_j)_{ij} &= \left(a I_n(a_{ij})_{ij} \right)^* \left(a I_n(a_{ij})_{ij} \right) \\ &\leq \| (a I_n)^* a I_n \| (a_i^* a_j)_{ij} \\ &= \|a^* a\| (a_i^* a_j)_{ij}, \end{aligned}$$

where the last line follows from the fact that for any elements of a C^* -algebra, a, b , we have $0 \leq b^* a^* a b \leq \|a^* a\| b^* b$.

Now, this gives

$$\begin{aligned} \left\langle \pi(a) \left(\sum_{j=1}^n a_j \otimes x_j \right), \pi(a) \left(\sum_{i=1}^n a_i \otimes x_i \right) \right\rangle &= \sum_{i,j=1}^n \langle \pi(a_i^* a^* a a_j) x_j, x_i \rangle_{\mathcal{H}} \\ &\leq \|a^* a\| \sum_{i,j=1}^n \langle \phi(a_i^* a_j) x_j, x_i \rangle \\ &= \|a\|^2 \left\langle \sum_{j=1}^n a_j \otimes x_j, \sum_{i=1}^n a_i \otimes x_i \right\rangle. \end{aligned}$$

Thus, $\pi(a)$ vanishes on N , meaning it induces a quotient map that we will write as $\tilde{\pi}(a)$. The above inequality shows that $\tilde{\pi}(a)$ is bounded, with $\|\tilde{\pi}(a)\| \leq \|a\|$. Thus, $\tilde{\pi}(a)$ extends to a bounded linear operator on \mathcal{K} , denoted $\tilde{\pi}(a)$.

Now, the map $\tilde{\pi}: A \rightarrow \mathcal{B}(\mathcal{K})$ is a unital $*$ -homomorphism.

Define $V: \mathcal{H} \rightarrow \mathcal{K}$ by $V(x) = 1 \otimes x + N$. Then, since

$$\begin{aligned} \|Vx\|^2 &= \langle 1 \otimes x, 1 \otimes x \rangle \\ &= \langle \phi(1)x, x \rangle_{\mathcal{H}} \\ &\leq \|\phi(1)\| \|x\|^2, \end{aligned}$$

V is bounded. Furthermore,

$$\begin{aligned} \|V\|_{\text{op}}^2 &= \sup_{x \in \mathcal{B}_{\mathcal{H}}} \langle \phi(1)x, x \rangle \\ &= \|\phi(1)\|. \end{aligned}$$

Finally, we see that

$$\begin{aligned} \langle V^* \tilde{\pi}(a) V x, y \rangle &= \langle (\pi(a) 1) \otimes x, 1 \otimes y \rangle_{\mathcal{H}} \\ &= \langle \phi(a)x, y \rangle_{\mathcal{H}}, \end{aligned}$$

so that $V^* \tilde{\pi}(a) V = \phi(a)$. □

There are some remarks to be made. First, any map of the form $\phi(a) = V^*\pi(a)V$ is already completely positive, so Stinespring's dilation is a complete characterization of completely positive maps from any C^* -algebra into any $\mathcal{B}(\mathcal{H})$. Furthermore, if ϕ is unital, then V is an isometry, and we may identify \mathcal{H} with $V\mathcal{H} \subseteq \mathcal{K}$. This identification gives V^* as the projection of \mathcal{K} onto \mathcal{H} , or $P_{\mathcal{H}}$. Thus,

$$\phi(a) = P_{\mathcal{H}}\pi(a)|_{\mathcal{H}}.$$

If $T \in \mathcal{B}(\mathcal{K})$, then $P_{\mathcal{H}}T|_{\mathcal{H}}$ is called the compression of T to \mathcal{H} . We may decompose $\mathcal{K} = \mathcal{H} \oplus \mathcal{H}^\perp$, and consider T as the 2×2 operator matrix whose compression is equal to the $(1, 1)$ entry of the operator matrix. Thus, Stinespring's dilation shows that every completely positive map into $\mathcal{B}(\mathcal{H})$ is the compression to \mathcal{H} of a $*$ -homomorphism into a Hilbert space that contains \mathcal{H} .

Additionally, Stinespring's dilation is a generalization of the GNS construction, which was used to convert from states to representations of C^* -algebras as subalgebras of $\mathcal{B}(\mathcal{H})$. In particular, if $\mathcal{H} = \mathbb{C}$, then the isometry $V: \mathbb{C} \rightarrow \mathcal{K}$ is determined by $V(1) = x$ and

$$\begin{aligned} \phi(a) &= \phi(a)(1) \cdot 1 \\ &= V^*\pi(a)V(1) \cdot 1 \\ &= \langle \pi(a)V(1), V(1) \rangle_{\mathcal{K}} \\ &= \langle \pi(a)x, x \rangle. \end{aligned}$$

Furthermore, if we reread the proof with $\mathcal{H} = \mathbb{C}$ and $A \otimes \mathbb{C} = A$, we recover the proof of the GNS representation of states.

Finally, if \mathcal{H} and A are separable, then so too is \mathcal{K} , and if \mathcal{H} and A are finite-dimensional, then so too is \mathcal{K} .

Now, we turn our attention to the uniqueness of the Stinespring representations, (π, V, \mathcal{K}) . Given one of these Stinespring representations, (π, V, \mathcal{K}) , we may consider \mathcal{K}_1 to be the closed linear span of $\pi(A)V\mathcal{H}$, which reduces $\pi(A)$, so that the restriction of π to \mathcal{K}_1 defines a $*$ -homomorphism $\pi_1: A \rightarrow \mathcal{B}(\mathcal{K}_1)$.

Now, $V\mathcal{H} \subseteq \mathcal{K}_1$, so that $\phi(a) = V^*\pi(a)V$. Therefore, $(\pi_1, V, \mathcal{K}_1)$ is also a Stinespring representation, where \mathcal{K}_1 is the closed linear span of $\pi_1(A)V\mathcal{H}$.

If our Stinespring representation also has the property that $\mathcal{K}_1 = \overline{\text{span}}(\pi(A)V\mathcal{H})$, then we call the triple a *minimal* Stinespring representation.

Proposition: Let A be a C^* -algebra, and let $\phi: A \rightarrow \mathcal{B}(\mathcal{H})$ be a completely positive map. Let $(\pi_i, V_i, \mathcal{K}_i)$ be two minimal Stinespring representations for ϕ .

Then, there exists a unitary map $U: \mathcal{K}_1 \rightarrow \mathcal{K}_2$ such that $UV_1 = V_2$, and $U\pi_1U^* = \pi_2$.

Proof. If U exists, then we must necessarily have

$$U\left(\sum_i \pi_1(a_i)V_1h_i\right) = \sum_i \pi_2(a_i)V_2h_i,$$

so it is sufficient to verify that the above formula gives a well-defined isometry. By the minimality condition, U will have dense range, hence onto.

Now, note that

$$\begin{aligned} \left\|\sum_i \pi_1(a_i)V_1h_i\right\|^2 &= \sum_{i,j} \langle V_1\pi_1(a_i^*a_j)V_1h_j, h_i \rangle \\ &= \sum_{i,j} \langle \phi(a_i^*a_j)h_j, h_i \rangle \end{aligned}$$

$$= \left\| \sum_i \pi_2(a_i) V_2 h_i \right\|^2,$$

so U is isometric. □

Arveson's Extension Theorem(s)

We start by recalling the fact that we can identify elements of the tensor product of two Banach spaces, $X \otimes Y$, with maps in $\mathcal{B}(X, Y^*)$.

Fix $x \in X$ and $y \in Y$. Define a linear functional $x \otimes y \in \mathcal{B}(X, Y^*)^*$ by $(x \otimes y)(L) = L(x)(y)$. Here, $L(x)$ is a linear functional on Y .

Since $|x \otimes y(L)| \leq \|L\| \|x\| \|y\|$. We see that $x \otimes y \in \mathcal{B}(X, Y^*)^*$, with $\|x \otimes y\| \leq \|x\| \|y\|$. In fact, it can be shown that $\|x \otimes y\| = \|x\| \|y\|$.

We may verify that $x \otimes y$ is a bilinear map. Let Z be the closed linear span in $\mathcal{B}(X, Y^*)^*$ of the elementary tensors, and we may identify Z with a cross-norm completion of $X \otimes Y$ (but we will not use that here). For now, we use the following result.

Lemma: The space $\mathcal{B}(X, Y^*)$ is isometrically isomorphic to Z^* with duality given by

$$\langle L, x \otimes y \rangle = (x \otimes y)(L).$$

Proof. We show that this map is surjective. Let $f \in Z^*$ be fixed, and for each x , define $f_x: Y \rightarrow \mathbb{C}$ by $f_x(y) = f(x \otimes y)$. Then, since $|f_x(y)| \leq \|f\| \|x\| \|y\|$, $f_x \in Y^*$.

If we set $L(x) = f_x$, then $L: X \rightarrow Y^*$ is bounded with $\|L\| \leq \|f\|$, so $L \in \mathcal{B}(X, Y^*)$ with the correspondence $L \mapsto F$. □

We call the weak* topology on $\mathcal{B}(X, Y^*)$ the bounded weak topology (or BW topology).

Lemma: Let $(L_\lambda)_\lambda$ be a bounded net in $\mathcal{B}(X, Y)$. Then, L_λ converges to L in the BW topology if and only if $L_\lambda(x)$ converges weakly to $L(x)$ for all $x \in X$.

Proof. If $L_\lambda \xrightarrow{\text{BW}} L$, then

$$\begin{aligned} L_\lambda(x)(y) &= \langle L_\lambda, x \otimes y \rangle \\ &\rightarrow \langle L, x \otimes y \rangle \\ &= L(x)(y) \end{aligned}$$

for all $y \in Y$, so that $L_\lambda(x) \xrightarrow{w} L(x)$ for all x .

Conversely, if $L_\lambda(x) \xrightarrow{w} L(x)$ for all $x \in X$, then $\langle L_\lambda, x \otimes y \rangle$ converges to $\langle L, x \otimes y \rangle$ for all x and y , hence on the linear span of the elementary tensors. However, since the net is bounded, it converges on the closed linear span. □

If \mathcal{H} is a Hilbert space, then $\mathcal{B}(\mathcal{H})$ is the dual of a Banach space, known as the trace class operators, $L_1(\mathcal{B}(\mathcal{H}))$, with the trace norm $\|T\|_{\text{tr}} = \text{tr}(|T|)$.

Under the duality, an operator $A \in \mathcal{B}(\mathcal{H})$ is identified with the linear functional $\text{tr}(AT)$ for some $T \in L_1(\mathcal{B}(\mathcal{H}))$. If $h, k \in \mathcal{H}$, define $\theta_{h,k}$ to be the rank-one bounded operator $\theta_{h,k}(x) = \langle x, k \rangle h$.

The linear span of the $\theta_{x,y}$ is dense in $L_1(\mathcal{B}(\mathcal{H}))$ with the trace norm. For $A \in \mathcal{B}(\mathcal{H})$, we have

$$\text{tr}(A\theta_{h,k}) = \langle Ah, k \rangle.$$

Proof. Let X be a Banach space, and let \mathcal{H} be a Hilbert space. A bounded net $(L_\lambda)_\lambda$ in $\mathcal{B}(X, \mathcal{B}(\mathcal{H}))$ converges in the BW topology to L if and only if $\langle L_\lambda(x)h, k \rangle \rightarrow \langle L(x)h, k \rangle$ for all $h, k \in \mathcal{H}$ and $x \in X$. \square

Proof. We know that $(L_\lambda)_\lambda \xrightarrow{\text{BW}} L$ if and only if $\text{tr}(L_\lambda(x)T) \rightarrow \text{tr}(L(x)T)$ for all $T \in L_1(\mathcal{B}(\mathcal{H}))$ and $x \in X$. However, since the net is bounded, we only need to consider the case of $T = \theta_{h,k}$. \square

In other words, BW convergence is pointwise WOT convergence.ⁱⁱⁱ Now, we consider some subspace we will use to establish Arveson's extension theorem.

Definition. Let A be a C^* -algebra, S an operator system, and M a subspace. We define

$$\begin{aligned} B_r(M, \mathcal{H}) &:= \{L \in \mathcal{B}(M, \mathcal{B}(\mathcal{H})) \mid \|L\| \leq r\} \\ CB_r(M, \mathcal{H}) &:= \{L \in \mathcal{B}(M, \mathcal{B}(\mathcal{H})) \mid \|L\|_{\text{cb}} \leq r\} \\ CP_r(S, \mathcal{H}) &:= \{L \in \mathcal{B}(S, \mathcal{B}(\mathcal{H})) \mid L \text{ is completely positive, } \|L\| \leq r\} \\ CP(S, \mathcal{H}; P) &:= \{L \in \mathcal{B}(S, \mathcal{B}(\mathcal{H})) \mid L \text{ is completely positive, } L(1) = P\}. \end{aligned}$$

Theorem: Let A be a C^* -algebra, S a closed operator system, and M a closed subspace. Then, each of the above four sets is BW-compact.

Proof. Since BW is a weak* topology, the set $B_r(M, \mathcal{H})$, being BW-closed and norm-bounded, is thus compact by the Banach-Alaoglu theorem. Thus, it is enough to show that the remaining sets are subsets of this set.

Let $(L_\lambda)_\lambda$ be a net in $CB_r(M, \mathcal{H})$, and let $(L_\lambda)_\lambda \rightarrow \lambda$.

If $(a_{ij})_{ij} \in \text{Mat}_n(M)$, and $x = x_1 \oplus \cdots \oplus x_n$, $y = y_1 \oplus \cdots \oplus y_n$, are in $\mathcal{H} \oplus \cdots \oplus \mathcal{H}$, then

$$\langle (L(a_{ij}))_{ij} x, y \rangle = \lim_\lambda \langle (L_\lambda(a_{ij}))_{ij} x, y \rangle,$$

so that

$$\|(L(a_{ij}))_{ij}\| \leq r \|(a_{ij})_{ij}\|$$

for all n , meaning

$$\|L\|_{\text{cb}} \leq r.$$

A similar process holds for the other sets. \square

Before we go to Arveson's extension theorem in the general case, we start with the case of maps into $\text{Mat}_n(\mathbb{C})$.

Definition. Let M be an operator space, and let $\{e_j\}_{j=1}^n$ be the canonical basis for \mathbb{C}^n . If $A \in \text{Mat}_n(\mathbb{C})$, we let $A_{(i,j)} := \langle A e_j, e_i \rangle$.

If $\phi: M \rightarrow \text{Mat}_n(\mathbb{C})$ is a linear map, we associate a linear functional s_ϕ , defined by

$$s_\phi((a_{ij})_{ij}) = \frac{1}{n} \sum_{i,j=1}^n \langle \phi((a_{ij})_{ij}) e_j, e_i \rangle.$$

Alternatively, if we let $x \in \mathbb{C}^n \oplus \cdots \oplus \mathbb{C}^n$ be defined by $x = e_1 \oplus \cdots \oplus e_n$, we may define

$$s_\phi((a_{ij})_{ij}) = \frac{1}{n} \langle \phi_n((a_{ij})_{ij}) x, x \rangle$$

ⁱⁱⁱYes, there are two modifiers here.

It can be verified that $\phi \mapsto s_\phi$ is a linear map between $\mathcal{L}(M, \text{Mat}_n(\mathbb{C}))$ and $\mathcal{L}(\text{Mat}_n(M), \mathbb{C})$. If M is unital, and $\phi(1) = 1$, then $s_\phi(1) = 1$.

Finally, if $s: \text{Mat}_n(M) \rightarrow \mathbb{C}$, then we may define $\phi_s: M \rightarrow \text{Mat}_n(\mathbb{C})$ by

$$\langle \phi_s(a)e_j, e_i \rangle = ns(a \otimes e_{ij}),$$

where $a \otimes e_{ij}$ is the element of $\text{Mat}_n(M)$ that has a in row i and column j , and is 0 elsewhere. The maps $\phi \mapsto s_\phi$ and $s \mapsto \phi_s$ are mutual inverses.

Exercise (Krein's Theorem): Let S be an operator system contained in the C^* -algebra A . Let $\phi: S \rightarrow \mathbb{C}$ be positive. Show that ϕ can be extended to a positive map on A .

Solution: We may extend ϕ to a positive map on A by defining $\psi: A \rightarrow \mathbb{C}$ by defining $\psi|_S = \phi$ and $\psi|_{A \setminus S} = 0$.

Theorem: Let A be a unital C^* -algebra, let S be an operator system in A , and let $\phi: S \rightarrow \text{Mat}_n(\mathbb{C})$. The following are equivalent:

- (i) ϕ is completely positive;
- (ii) ϕ is n -positive;
- (iii) s_ϕ is positive.

Proof. Since (i) implies (ii), and (ii) implies (iii) by the definition of s_ϕ as

$$s_\phi\left(\left(a_{ij}\right)_{ij}\right) = \frac{1}{n} \left\langle \phi_n\left(\left(a_{ij}\right)_{ij}\right) x, x \right\rangle,$$

where $x = e_1 \oplus \cdots \oplus e_n$, we have that s_ϕ is positive.

Suppose s_ϕ is positive. Then, we may extend s_ϕ from $\text{Mat}_n(S)$ to a positive linear functional s on $\text{Mat}_n(A)$. The map $\psi: A \rightarrow \text{Mat}_n(\mathbb{C})$ associated to s extends s_ϕ .

If we can prove that ψ is completely positive, then $\phi = \psi|_S$ is completely positive.

To show that ψ is m -positive, we may consider an element of the form $(a_i^* a_j)_{ij} \in \text{Mat}_m(A)$.

Since $\psi_m\left((a_i^* a_j)_{ij}\right)$ acts on \mathbb{C}^{mn} , it is sufficient to take $x = x_1 \oplus \cdots \oplus x_m$, where $x_j = \sum_{k=1}^n \lambda_{jk} e_k$, and find

$$\begin{aligned} \left\langle \psi_m\left((a_i^* a_j)_{ij}\right) x, x \right\rangle &= \sum_{i,j} \left\langle \psi(a_i^* a_j) x, x \right\rangle \\ &= \sum_{i,j,k,\ell} \lambda_{jk} \overline{\lambda_{i\ell}} \left\langle \psi(a_i^* a_j) e_k, e_\ell \right\rangle \\ &= \sum_{i,j,k,\ell} \lambda_{jk} \overline{\lambda_{i\ell}} s(a_i^* a_j \otimes e_{\ell k}). \end{aligned}$$

Let A_i be the $n \times n$ matrix with row $\lambda_{i1}, \dots, \lambda_{in}$ and 0 elsewhere. Then,

$$A_i^* A_j = \sum_{k,\ell} \overline{\lambda_{i\ell}} \lambda_{jk} e_{\ell k}.$$

Therefore, we obtain

$$\begin{aligned} \left\langle \psi_m\left((a_i^* a_j)_{ij}\right) x, x \right\rangle &= \sum_{i,j} s(a_i^* a_j \otimes A_i^* A_j) \\ &= s\left(\left(\sum_i a_i \otimes A_i\right)^* \left(\sum_j a_j \otimes A_j\right)\right), \end{aligned}$$

which is positive since s is positive. Thus, ψ is m -positive for all m . □

Theorem: Let A be a unital C^* -algebra, $S \subseteq A$ an operator system, and $\phi: S \rightarrow \text{Mat}_n(\mathbb{C})$ completely positive.

Then, there exists a completely positive map $\psi: A \rightarrow \text{Mat}_n(\mathbb{C})$ that extends ϕ .

Proof. Let $s_\phi: \text{Mat}_n(S) \rightarrow \mathbb{C}$ associated with ϕ . Extend s_ϕ to a positive linear functional s on $\text{Mat}_n(A)$ by Krein's theorem.

The map $\psi: A \rightarrow \text{Mat}_n(\mathbb{C})$ is completely positive. Since s extends s_ϕ , ψ extends ϕ . \square

We can now show the case for $\mathbb{B}(\mathcal{H})$, not just the case of matrix algebras.

Theorem (Arveson's Extension Theorem): Let A be a C^* -algebra, $S \subseteq A$ an operator system, and $\phi: S \rightarrow \mathbb{B}(\mathcal{H})$ a completely positive map.

Then, there exists $\psi: A \rightarrow \mathbb{B}(\mathcal{H})$ extending ϕ . This implies that $\mathbb{B}(\mathcal{H})$ is injective in the category of C^* -algebras with completely positive maps.

$$\begin{array}{ccccc} 0 & \longrightarrow & S & \xrightarrow{\iota} & A \\ & & \phi \downarrow & \swarrow \psi & \\ & & \mathbb{B}(\mathcal{H}) & & \end{array}$$

Theorem: Let \mathcal{F} be a finite-dimensional subspace of \mathcal{H} , and let $\phi_{\mathcal{F}}: S \rightarrow \mathbb{B}(\mathcal{F})$ be the compression $\phi_{\mathcal{F}}(a) = P_{\mathcal{F}}\phi(a)|_{\mathcal{F}}$, where $P_{\mathcal{F}}$ is the projection onto \mathcal{F} .

Since $\mathbb{B}(\mathcal{F}) \cong \text{Mat}_n(\mathbb{C})$ for some n , there exists a completely positive map $\psi_{\mathcal{F}}: A \rightarrow \mathbb{B}(\mathcal{F})$ that extends $\phi_{\mathcal{F}}$. Let $\psi'_{\mathcal{F}}: A \rightarrow \mathbb{B}(\mathcal{H})$ be defined by $\psi'_{\mathcal{F}}(a) = \psi_{\mathcal{F}}(a)$ on \mathcal{F} and equal to 0 on \mathcal{F}^\perp .

The set of finite-dimensional subspaces of \mathcal{H} is a directed set under inclusion, so $(\psi'_{\mathcal{F}})_{\mathcal{F}}$ is a net in $\text{CP}_r(A, \mathcal{H})$, where $r = \|\phi\|$.

Since the set $\text{CP}_r(A, \mathcal{H})$ is compact, we may choose a subnet which converges to some $\psi \in \text{CP}_r(A, \mathcal{H})$.

We claim that ψ is the desired extension. If $a \in S$ and $x, y \in \mathcal{H}$, let $\mathcal{F} = \text{span}(x, y)$. Then, for any $\mathcal{F}_1 \supseteq \mathcal{F}$, we have $\langle \phi(a)x, y \rangle = \langle \psi'_{\mathcal{F}_1}(a)x, y \rangle$, and since \mathcal{F}_1 is cofinal, $\langle \phi(a)x, y \rangle = \langle \psi(a)x, y \rangle$.

Corollary: Let A be a C^* -algebra, $M \subseteq A$ a unital subspace, and $\phi: M \rightarrow \mathbb{B}(\mathcal{H})$ a unital, completely contractive map. Then, there exists a completely positive map $\psi: A \rightarrow \mathbb{B}(\mathcal{H})$ that extends ϕ .

Ideals of Operators

We need a bit more theory about $\mathbb{B}(\mathcal{H})$, specifically related to the trace class/Hilbert–Schmidt operators and the noncommutative dual spaces, as well as their induced topologies.

Polar and Singular Value Decomposition

Just as a nonzero complex number $z \in \mathbb{C}$ can be written as $z = \omega|z|$, where $\omega \in \mathbb{T}$ is equal to $\text{sgn}(z)$, or $\frac{z}{|z|}$, we can decompose an operator into a product of a partial isometry and a positive operator.

Lemma: Let \mathcal{H} be a Hilbert space, $T \in \mathbb{B}(\mathcal{H})$.

- (1) For all $\xi \in \mathcal{H}$, $\|T\xi\| = \||T|\xi\|$, so that $\ker(|T|) = \ker(T)$.
- (2) We have $\overline{\text{Ran}}(|T|) = \ker(|T|)^\perp = \ker(T)^\perp$.

Proof.

(1) If $\xi \in \mathcal{H}$, then

$$\begin{aligned} \||T|\xi\|^2 &= \langle |T|\xi, |T|\xi \rangle \\ &= \langle |T|^* |T| \xi, \xi \rangle \\ &= \langle |T|^2 \xi, \xi \rangle \\ &= \langle T^* T \xi, \xi \rangle \\ &= \|T\xi\|^2, \end{aligned}$$

as T is self-adjoint, and $T^*T = |T|^2$. Thus, $\ker(|T|) = \ker(T)$.

(2) We have

$$\begin{aligned} \overline{\text{Ran}}(T) &= \ker(|T|^*)^\perp \\ &= \ker(|T|)^\perp. \end{aligned}$$

□

Proposition (Polar Decomposition): Let \mathcal{H} be a Hilbert space, and let $T \in \mathcal{B}(\mathcal{H})$. Then, there exists a unique partial isometry $V \in \mathcal{B}(\mathcal{H})$ such that $T = V|T|$ and $\ker(T) = \ker(V)$. Moreover, $V^*T = |T|$, and if T is invertible, then $V = T|T|^{-1}$ is unitary, and belongs to $C^*(T)$.

Proof. We see that the map $|T|\xi \mapsto T\xi$ from $\text{Ran}(|T|)$ to $\text{Ran}(T)$, is well-defined, linear, and isometric, so it extends by continuity to an isometric linear map $V_0: \overline{\text{Ran}}(|T|) \rightarrow \overline{\text{Ran}}(T)$. Define

$$\begin{aligned} V: \ker(T)^\perp \oplus \ker(T) &\rightarrow \mathcal{H} \\ \xi \oplus \eta &\mapsto V_0\xi. \end{aligned}$$

By construction, $V|T| = T$ and $\ker(V) = \ker(T)$. Since $V|_{\ker(V)^\perp} = V_0$ is isometric, V is a partial isometry with initial space $\ker(T)^\perp$ and final space $\overline{\text{Ran}}(T)$.

Now, since V^*V is the orthogonal projection onto the initial space $\overline{\text{Ran}}(|T|)$, we have

$$\begin{aligned} V^*T &= V^*V|T| \\ &= |T|. \end{aligned}$$

For uniqueness, suppose W is a partial isometry satisfying $T = W|T|$ with $\ker(W) = \ker(T)$. Then, for all $\xi \in \mathcal{H}$, we have

$$\begin{aligned} W(|T|\xi) &= T\xi \\ &= V(|T|\xi), \end{aligned}$$

so W and V agree on $\text{Ran}(|T|)$, and by continuity, $\overline{\text{Ran}}(|T|)$. Since both W and V send $\ker(T)$ to 0, W and V agree on the orthogonal complement $\overline{\text{Ran}}(|T|)^\perp$ as well. Thus, $W = V$.

Now, if T is invertible, then so is $|T|$, so $T|T|^{-1} = V$. Since $\text{Ran}(T) = \text{Ran}(|T|) = \mathcal{H}$, the operator V is a surjective isometry, hence unitary.

Furthermore, $|T| \in C^*(T)$, and $|T|^{-1} \in C^*(|T|) \subseteq C^*(T)$, so that $V = T|T|^{-1} \in C^*(T)$. □

Fact. Let $T = V|T|$ be the polar decomposition of $T \in \mathcal{B}(\mathcal{H})$. Then, $|T^*| = V|T|V^*$.

Proof. We see that

$$\begin{aligned} (V|T|V^*)(V|T|V^*) &= TV^*TV^* \\ &= T|T|V^* \\ &= T(V|T|)^* \\ &= TT^*. \end{aligned}$$

Since $|T|$ is positive, and positivity is preserved by conjugation, $V|T|V^*$ is also positive, and since $(V|T|V^*)^2 = TT^*$, uniqueness of square roots implies that $V|T|V^* = (TT^*)^{1/2} = |T^*|$. \square

One of the primary uses of the polar decomposition is in establishing the singular value decomposition.

Proposition (Singular Value Decomposition): Let $T \in \mathbb{K}(\mathcal{H})$ be compact. There is a possibly finite sequence $(\mu_k)_k \in c_0$ with $\mu_k > 0$, and two possibly finite orthonormal sequences $(e_k)_k$ and $(f_k)_k$ in \mathcal{H} such that

$$T = \sum_k \mu_k \theta_{f_k, e_k},$$

with convergence in operator norm. Moreover, $\|T\|_{\text{op}} = \max_k |\mu_k|$.

If T is finite-rank, then the sum is finite.

The scalars $(\mu_k)_k$ are called the singular values of T .

Proof. Let $T = V|T|$ be the polar decomposition. Then, $|T| = V^*T$ is compact, as $\mathbb{K}(\mathcal{H})$ is an ideal. Similarly, if T is finite-rank, then so is $|T|$.

From the spectral theorem, we know that

$$|T| = \sum_k \mu_k \theta_{e_k, e_k},$$

where $(e_k)_k$ is an orthonormal sequence and $(\mu_k)_k$ is a sequence of necessarily positive scalars (as $|T|$ is a positive operator). The sum is finite if T is finite rank.

Now, we set $f_k = Ve_k$ for each k . Thus, we have

$$\begin{aligned} T &= V|T| \\ &= V \left(\sum_k \mu_k \theta_{e_k, e_k} \right) \\ &= \sum_k \mu_k V \theta_{e_k, e_k} \\ &= \sum_k \mu_k \theta_{Ve_k, e_k} \\ &= \sum_k \mu_k \theta_{f_k, e_k}. \end{aligned}$$

Now, we must show that $(f_k)_k$ is orthonormal. Since e_k is an eigenvector for $|T|$, and each μ_k is nonzero, each e_k belongs to $\text{Ran}(|T|)$. Since V^*V is the projection onto the initial space $\overline{\text{Ran}}(|T|)$, we have $V^*Ve_k = e_k$, so

$$\begin{aligned} \langle f_k, f_\ell \rangle &= \langle Ve_k, Ve_\ell \rangle \\ &= \langle V^*Ve_k, e_\ell \rangle \\ &= \langle e_k, e_\ell \rangle \end{aligned}$$

$$= \delta_{k\ell}.$$

Now, since $|T|$ is diagonalizable, its operator norm is the supremum of its eigenvalues, $\| |T| \|_{\text{op}} = \sup_k |\mu_k|$, and since $\|T\|_{\text{op}} = \| |T| \|_{\text{op}}$, and $(\mu_k)_k \in c_0$, the supremum is attained. \square

Hilbert–Schmidt Operators

We start with the noncommutative analogue of ℓ_2 .

Lemma: Let \mathcal{H} be a Hilbert space, $T, S \in \mathcal{B}(\mathcal{H})$, and let $(e_\alpha)_\alpha$ and $(f_\gamma)_\gamma$ be orthonormal bases for \mathcal{H} . Then,

- (1) $\sum_\alpha \|Te_\alpha\|^2 = \sum_\alpha \|T^*e_\alpha\|^2$ (invariant under adjoints);
- (2) $\sum_\alpha \|Te_\alpha\|^2 = \sum_\gamma \|Tf_\gamma\|^2$ (independent of basis choice).

Proof. Note that by Parseval's identity, we have

$$\|Te_\alpha\|^2 = \sum_\beta |\langle Te_\alpha, e_\beta \rangle|^2 \quad (*)$$

$$= \sum_\gamma |\langle Te_\alpha, f_\gamma \rangle|^2. \quad (**)$$

- (1) By Fubini's theorem and (*), we have

$$\begin{aligned} \sum_\alpha \|Te_\alpha\|^2 &= \sum_\alpha \sum_\beta |\langle Te_\alpha, e_\beta \rangle|^2 \\ &= \sum_\alpha \sum_\beta |\langle e_\alpha, T^*e_\beta \rangle|^2 \\ &= \sum_\beta \sum_\alpha |\langle T^*e_\beta, e_\alpha \rangle|^2 \\ &= \sum_\beta \|T^*e_\beta\|^2 \\ &= \sum_\alpha \|T^*e_\alpha\|^2. \end{aligned}$$

- (2) The proof commences similarly, substituting (**) instead of (*), and using the result in (1).

\square

Definition. Let \mathcal{H} be a Hilbert space. We define

$$\|T\|_{\text{HS}} = \left(\sum_{\alpha \in A} \|Te_\alpha\|^2 \right)^{1/2},$$

where $(e_\alpha)_\alpha$ is an orthonormal basis for \mathcal{H} . The class of Hilbert–Schmidt operators is

$$L_2(\mathcal{B}(\mathcal{H})) := \{T \in \mathcal{B}(\mathcal{H}) \mid \|T\|_{\text{HS}} < \infty\}.$$

Lemma: Let \mathcal{H} be a Hilbert space with orthonormal bases $(e_\alpha)_\alpha$ and $(f_\gamma)_\gamma$. Let $S, T \in L_2(\mathcal{B}(\mathcal{H}))$. Then,

- (1) The series $\sum_\alpha \langle Te_\alpha, Se_\alpha \rangle$ is summable;
- (2) $\sum_\alpha \langle Te_\alpha, Se_\alpha \rangle = \sum_\alpha \langle S^*e_\alpha, Te_\alpha \rangle$;
- (3) $\sum_\alpha \langle Te_\alpha, Se_\alpha \rangle = \sum_\gamma \langle Tf_\gamma, Sf_\gamma \rangle$.

Proof. (1) For a finite collection F of basis elements, we use the Cauchy–Schwarz inequality in \mathcal{H} and $\ell_2^{|F|}$ to get

$$\begin{aligned} \sum_{\alpha \in F} |\langle T e_\alpha, S e_\alpha \rangle| &\leq \sum_{\alpha \in F} \|T e_\alpha\| \|S e_\alpha\| \\ &\leq \left(\sum_{\alpha \in F} \|T e_\alpha\|^2 \right)^{1/2} \left(\sum_{\alpha \in F} \|S e_\alpha\|^2 \right)^{1/2} \\ &\leq \|T\|_{\text{HS}} \|S\|_{\text{HS}}. \end{aligned}$$

Taking the supremum over all finite subsets, we have $\sum_{\alpha} |\langle T e_\alpha, S e_\alpha \rangle|$ is summable, so $\sum_{\alpha} \langle T e_\alpha, S e_\alpha \rangle$ is summable.

(2) Recalling the identity that

$$\langle x, y \rangle = \sum_{\alpha} \langle x, e_\alpha \rangle \langle e_\alpha, y \rangle,$$

we have

$$\begin{aligned} \sum_{\alpha} \langle T e_\alpha, S e_\alpha \rangle &= \sum_{\alpha} \sum_{\beta} \langle T e_\alpha, e_\beta \rangle \langle e_\beta, S e_\alpha \rangle \\ &= \sum_{\alpha} \sum_{\beta} \langle e_\alpha, T^* e_\beta \rangle \langle S^* e_\beta, e_\alpha \rangle \\ &= \sum_{\alpha} \sum_{\beta} \langle S^* e_\beta, e_\alpha \rangle \langle e_\alpha, T^* e_\beta \rangle \\ &= \sum_{\beta} \sum_{\alpha} \langle S^* e_\beta, e_\alpha \rangle \langle e_\alpha, T^* e_\beta \rangle \\ &= \sum_{\beta} \langle S^* e_\beta, T^* e_\beta \rangle \\ &= \sum_{\alpha} \langle S^* e_\alpha, T^* e_\beta \rangle. \end{aligned}$$

(3) Similarly,

$$\begin{aligned} \sum_{\alpha} \langle T e_\alpha, S e_\alpha \rangle &= \sum_{\alpha} \sum_{\gamma} \langle T e_\alpha, f_\gamma \rangle \langle f_\gamma, S e_\alpha \rangle \\ &= \sum_{\gamma} \sum_{\alpha} \langle S^* f_\gamma, e_\alpha \rangle \langle e_\alpha, T^* f_\gamma \rangle \\ &= \sum_{\gamma} \langle S^* f_\gamma, T^* f_\gamma \rangle \\ &= \sum_{\gamma} \langle T f_\gamma, S f_\gamma \rangle. \end{aligned}$$

□

Theorem (Properties of Hilbert–Schmidt Operators): Let \mathcal{H} be a Hilbert space.

- (1) The vector space $L_2(\mathcal{B}(\mathcal{H}))$ admits $\|\cdot\|_{\text{HS}}$ as a norm.
- (2) For $T \in \mathcal{B}(\mathcal{H})$, we have $\|T\|_{\text{op}} \|T\|_{\text{HS}}$, and $\|T\|_{\text{HS}} = \|T^*\|_{\text{HS}}$.

(3) If $T \in \mathcal{B}(\mathcal{H})$ and $S \in L_2(\mathcal{B}(\mathcal{H}))$,

$$\begin{aligned}\|TS\|_{\text{HS}} &\leq \|T\|_{\text{op}}\|S\|_{\text{HS}} \\ \|ST\|_{\text{HS}} &\leq \|S\|_{\text{HS}}\|T\|_{\text{op}}.\end{aligned}$$

Thus, $L_2(\mathcal{B}(\mathcal{H})) \subseteq \mathcal{B}(\mathcal{H})$ is an algebraic ideal.

(4) The form

$$\langle T, S \rangle_{\text{HS}} = \sum_{\alpha} \langle Te_{\alpha}, Se_{\alpha} \rangle,$$

where $(e_{\alpha})_{\alpha}$ is an orthonormal basis for \mathcal{H} , defines an inner product satisfying $\langle T, T \rangle_{\text{HS}} = \|T\|_{\text{HS}}^2$ and $\langle T, S \rangle = \langle S^*, T^* \rangle$.

(5) The pair $(L_2(\mathcal{B}(\mathcal{H})), \langle \cdot, \cdot \rangle_{\text{HS}})$ is a Hilbert space.

Proof.

(1) If $\lambda \in \mathbb{C}$, then $\|\lambda T\|_{\text{HS}} = |\lambda|\|T\|_{\text{HS}}$, so that λT is in $L_2(\mathcal{B}(\mathcal{H}))$ if $T \in L_2(\mathcal{B}(\mathcal{H}))$.

Now, let $(e_{\alpha})_{\alpha}$ be an orthonormal basis for \mathcal{H} , and let $T, S \in L_2(\mathcal{B}(\mathcal{H}))$. Then,

$$\begin{aligned}\|T + S\|_{\text{HS}} &= \left(\sum_{\alpha} \|(T + S)e_{\alpha}\|^2 \right)^{1/2} \\ &\leq \left(\sum_{\alpha} (\|Te_{\alpha}\| + \|Se_{\alpha}\|)^2 \right)^{1/2} \\ &\leq \left(\sum_{\alpha} \|Te_{\alpha}\|^2 \right)^{1/2} + \left(\sum_{\alpha} \|Se_{\alpha}\|^2 \right)^{1/2} \\ &= \|T\|_{\text{HS}} + \|S\|_{\text{HS}},\end{aligned} \tag{*}$$

where in (*), we used the triangle inequality in $\ell_2(A)$.

Finally, if $\|T\|_{\text{HS}} = 0$, then $Te_{\alpha} = 0$ for all $\alpha \in A$, whence $T = 0$.

(2) Let $x \in S_{\mathcal{H}}$. We may extend $\{x\}$ to an orthonormal basis $(e_{\alpha})_{\alpha}$ such that $e_{\alpha_0} = x$ for some α_0 . This gives

$$\begin{aligned}\|Tx\| &\leq \left(\sum_{\alpha} \|Te_{\alpha}\|^2 \right)^{1/2} \\ &= \|T\|_{\text{HS}}.\end{aligned}$$

Taking suprema, we get $\|T\|_{\text{op}} \leq \|T\|_{\text{HS}}$.

We showed $\|T\|_{\text{HS}} = \|T^*\|_{\text{HS}}$ implicitly in the earlier lemma.

(3) If $T \in \mathcal{B}(\mathcal{H})$ and $S \in L_2(\mathcal{B}(\mathcal{H}))$, we have

$$\begin{aligned}\|TS\|_{\text{HS}}^2 &= \sum_{\alpha} \|TSe_{\alpha}\|^2 \\ &\leq \sum_{\alpha} \|T\|_{\text{op}}^2 \|Se_{\alpha}\|^2\end{aligned}$$

$$= \|T\|_{\text{op}}^2 \|S\|_{\text{HS}}^2.$$

Taking square roots yields our desired results.

In the opposite direction, we have

$$\begin{aligned} \|ST\|_{\text{HS}} &= \|(ST)^*\|_{\text{HS}} \\ &\leq \|T^*\|_{\text{op}} \|S\|_{\text{HS}} \\ &= \|T\|_{\text{HS}} \|S\|_{\text{HS}}. \end{aligned}$$

Thus, $L_2(\mathcal{B}(\mathcal{H}))$ is a two-sided $*$ -ideal in $\mathcal{B}(\mathcal{H})$. Furthermore, if $T, S \in L_2(\mathcal{B}(\mathcal{H}))$, then

$$\begin{aligned} \|TS\|_{\text{HS}} &\leq \|T\|_{\text{op}} \|S\|_{\text{HS}} \\ &\leq \|T\|_{\text{HS}} \|S\|_{\text{HS}}, \end{aligned}$$

so $L_2(\mathcal{B}(\mathcal{H}))$ is a normed $*$ -algebra as well.

- (4) We know that $\langle T, S \rangle_{\text{HS}} = \sum_{\alpha} \langle T e_{\alpha}, S e_{\alpha} \rangle$ is summable and basis-independent. Linearity in the first coordinate follows from the definition of the inner product.

To see conjugate symmetry, we have

$$\begin{aligned} \langle S, T \rangle_{\text{HS}} &= \sum_{\alpha} \langle S e_{\alpha}, T e_{\alpha} \rangle \\ &= \sum_{\alpha} \overline{\langle T e_{\alpha}, S e_{\alpha} \rangle} \\ &= \overline{\sum_{\alpha} \langle T e_{\alpha}, S e_{\alpha} \rangle} \\ &= \overline{\langle T, S \rangle_{\text{HS}}}. \end{aligned}$$

Finally,

$$\begin{aligned} \langle T, T \rangle_{\text{HS}} &= \sum_{\alpha} \langle T e_{\alpha}, T e_{\alpha} \rangle \\ &= \sum_{\alpha} \|T e_{\alpha}\|^2 \\ &= \|T\|_{\text{HS}}^2. \end{aligned}$$

- (5) Let $(T_n)_n$ be a $\|\cdot\|_{\text{HS}}$ -Cauchy sequence in $L_2(\mathcal{B}(\mathcal{H}))$. Thus, $(T_n)_n$ is $\|\cdot\|_{\text{op}}$ -Cauchy, so there is $T \in \mathcal{B}(\mathcal{H})$ such that $(T_n)_n \xrightarrow{\|\cdot\|_{\text{op}}} T$.

We claim that $T \in L_2(\mathcal{B}(\mathcal{H}))$. Let $(e_{\alpha})_{\alpha}$ be an orthonormal basis in \mathcal{H} , and let $F \subseteq A$ be a finite subset. Since $(T_n)_n$ is $\|\cdot\|_{\text{HS}}$ -Cauchy, it is $\|\cdot\|_{\text{HS}}$ -bounded. Set $C := \sup_n \|T_n\|_{\text{HS}} < \infty$.

Using the triangle inequality in \mathcal{H} and $\ell_2^{|F|}$, we get

$$\begin{aligned} \left(\sum_{\alpha \in F} \|T e_{\alpha}\|^2 \right)^{1/2} &\leq \left(\sum_{\alpha \in F} (\|T e_{\alpha} - T_n e_{\alpha}\| + \|T_n e_{\alpha}\|)^2 \right)^{1/2} \\ &\leq \left(\sum_{\alpha \in F} \|T e_{\alpha} - T_n e_{\alpha}\|^2 \right)^{1/2} + \left(\sum_{\alpha \in F} \|T_n e_{\alpha}\|^2 \right)^{1/2} \end{aligned}$$

$$\leq \left(\sum_{\alpha \in F} \|T e_\alpha - T_n e_\alpha\|^2 \right)^{1/2} + C.$$

Letting $n \rightarrow \infty$, we have

$$\left(\sum_{\alpha \in F} \|T e_\alpha\|^2 \right)^{1/2} \leq C.$$

Now, taking the supremum over all finite $F \subseteq A$, we have $\|T\|_{HS} \leq C$.

Now, we claim that $\|T_n - T\|_{HS} \rightarrow 0$ as $n \rightarrow \infty$. Since $(T_n)_n$ is $\|\cdot\|_{HS}$ -Cauchy, we may choose $N \in \mathbb{N}$ such that for all $m, n \geq N$, we have $\|T_m - T_n\|_{HS} < \varepsilon$.

If $F \subseteq A$ is finite, with $m, n \geq N$, then

$$\sum_{\alpha \in F} \|T_m e_\alpha - T_n e_\alpha\|^2 < \varepsilon^2.$$

Taking $m \rightarrow \infty$, we have

$$\sum_{\alpha \in F} \|T e_\alpha - T_n e_\alpha\|^2 \leq \varepsilon^2,$$

and taking the supremum over all finite $F \subseteq A$, we get $\|T - T_n\|_{HS}^2 \leq \varepsilon$ for all $n \geq N$.

□

Proposition: Let \mathcal{H} be a Hilbert space. The following inclusions hold:

$$\mathbb{F}(\mathcal{H}) \subseteq L_2(\mathbb{B}(\mathcal{H})) \subseteq \mathbb{K}(\mathcal{H}).$$

Moreover, $\overline{\mathbb{F}(\mathcal{H})}^{\|\cdot\|_{HS}} = L_2(\mathbb{B}(\mathcal{H}))$.

Proof. Let $\xi, \eta \in \mathcal{H}$. Let $\theta_{\xi, \eta}$ be the rank-one bounded operator given by $\theta_{\xi, \eta}(x) = \langle x, \eta \rangle \xi$. We will show that $\theta_{\xi, \eta} \in L_2(\mathbb{B}(\mathcal{H}))$.

Let $(e_\alpha)_\alpha$ be an orthonormal basis for \mathcal{H} . Using Parseval's identity, we have

$$\begin{aligned} \|\theta_{\xi, \eta}\|_{HS} &= \left(\sum_{\alpha} \|(\theta_{\xi, \eta})(e_\alpha)\|^2 \right)^{1/2} \\ &= \left(\sum_{\alpha} \|\langle e_\alpha, \eta \rangle \xi\|^2 \right)^{1/2} \\ &= \left(\|\xi\|^2 \sum_{\alpha} |\langle e_\alpha, \eta \rangle|^2 \right)^{1/2} \\ &= \left(\|\xi\|^2 \|\eta\|^2 \right)^{1/2} \\ &= \|\xi\| \|\eta\|. \end{aligned}$$

Now, since $L_2(\mathbb{B}(\mathcal{H}))$ is a vector space, we have $\mathbb{F}(\mathcal{H}) = \text{span}(\{\theta_{\xi, \eta} \mid \xi, \eta \in \mathcal{H}\}) \subseteq L_2(\mathbb{B}(\mathcal{H}))$.

Finally, let $T \in L_2(\mathbb{B}(\mathcal{H}))$. There is a finite $F \subseteq A$ with $\sum_{\alpha \notin F} \|Te_\alpha\|^2 < \varepsilon^2$. We define $S \in \mathbb{F}(\mathcal{H})$ by

$$S := \sum_{\beta \in F} T\theta_{e_\beta, e_\beta}.$$

Note that

$$Se_\alpha = \begin{cases} 0 & \alpha \notin F \\ Te_\alpha & \alpha \in F. \end{cases}$$

Therefore,

$$\begin{aligned} \|T - S\|_{\text{HS}}^2 &= \sum_{\alpha \in A} \|Te_\alpha - Se_\alpha\|^2 \\ &= \sum_{\alpha \in F} \|Te_\alpha - Se_\alpha\|^2 + \sum_{\alpha \notin F} \|Te_\alpha - Se_\alpha\|^2 \\ &= \sum_{\alpha \notin F} \|Te_\alpha\|^2 \\ &< \varepsilon^2. \end{aligned}$$

Since $L_2(\mathbb{B}(\mathcal{H}))$ is $\|\cdot\|_{\text{HS}}$ -complete, we have $\overline{\mathbb{F}(\mathcal{H})}^{\|\cdot\|_{\text{HS}}} = L_2(\mathbb{B}(\mathcal{H}))$.

Furthermore, since $\|T - S\|_{\text{op}} < \varepsilon$, as the operator norm is dominated by the HS norm, we have $T \in \mathbb{F}(\mathcal{H})^{\|\cdot\|_{\text{op}}} = \mathbb{K}(\mathcal{H})$. \square

Proposition: Let \mathcal{H} be a Hilbert space. There is a unitary map $U: \mathcal{H} \otimes \overline{\mathcal{H}} \rightarrow L_2(\mathbb{B}(\mathcal{H}))$, where $\mathcal{H} \otimes \overline{\mathcal{H}}$ is endowed with the 2-norm, $\|x \otimes y\|^2 = \langle x \otimes y, x \otimes y \rangle = \langle x, x \rangle \langle y, y \rangle$.

The map U is defined by $U(\xi \otimes \bar{\eta}) = \theta_{\xi, \eta}$.

Proof. Consider the bilinear map $\mathcal{H} \times \overline{\mathcal{H}} \rightarrow \mathbb{F}(\mathcal{H})$ given by $(\xi, \bar{\eta}) \mapsto \theta_{\xi, \eta}$. This induces a linear map $U_0: \mathcal{H} \otimes \overline{\mathcal{H}} \rightarrow \mathbb{F}(\mathcal{H})$, given by $\xi \otimes \bar{\eta} \mapsto \theta_{\xi, \eta}$. This map is surjective since $\mathbb{F}(\mathcal{H})$ is the linear span of the rank-one operators.

Now, let $\xi, \xi', \eta, \eta' \in \mathcal{H}$, and suppose $(e_\alpha)_\alpha$ is an orthonormal basis for \mathcal{H} . We compute

$$\begin{aligned} \langle \theta_{\xi, \eta}, \theta_{\xi', \eta'} \rangle &= \sum_{\alpha \in A} \langle \theta_{\xi, \eta}(e_\alpha), \theta_{\xi', \eta'}(e_\alpha) \rangle \\ &= \sum_{\alpha \in A} \langle \langle e_\alpha, \eta \rangle \xi, \langle e_\alpha, \eta' \rangle \xi' \rangle \\ &= \sum_{\alpha \in A} \langle e_\alpha, \eta \rangle \langle \eta', e_\alpha \rangle \langle \xi, \xi' \rangle \\ &= \langle \eta', \eta \rangle \langle \xi, \xi' \rangle \\ &= \langle \xi, \xi' \rangle \overline{\langle \eta, \eta' \rangle} \\ &= \langle \xi \otimes \eta, \xi' \otimes \eta' \rangle. \end{aligned}$$

By linearity, the map $U_0: \mathcal{H} \otimes \overline{\mathcal{H}} \rightarrow \mathbb{F}(\mathcal{H})$ is an isomorphism of inner product spaces. By continuity, it extends to the map $U: \mathcal{H} \otimes \overline{\mathcal{H}} \rightarrow \overline{\mathbb{F}(\mathcal{H})}^{\|\cdot\|_2} = L_2(\mathbb{B}(\mathcal{H}))$. \square

Trace-Class Operators

Now, we will examine the noncommutative analogue of ℓ_1 . Recall that for any positive operator $T \in \mathcal{B}(\mathcal{H})_+$, there is a unique $S \in \mathcal{B}(\mathcal{H})_+$ such that $S^2 = T$, called $T^{1/2} := S$. We define the absolute value of an operator to be $|T| := (T^*T)^{1/2}$.

Definition. Let \mathcal{H} be a Hilbert space. We define

$$\|T\|_{\text{tr}} = \left\| |T|^{1/2} \right\|_{\text{HS}}^2.$$

The collection of trace-class operators is the set

$$L_1(\mathcal{B}(\mathcal{H})) := \{T \in \mathcal{B}(\mathcal{H}) \mid \|T\|_{\text{tr}} < \infty\}.$$

Using the Hilbert–Schmidt inner product formula, we may find

$$\begin{aligned} \|T\|_{\text{tr}} &= \left\| |T|^{1/2} \right\|_{\text{HS}}^2 \\ &= \left\langle |T|^{1/2}, |T|^{1/2} \right\rangle_{\text{HS}} \\ &= \sum_{\alpha \in A} \left\langle |T|^{1/2} e_{\alpha}, |T|^{1/2} e_{\alpha} \right\rangle \\ &= \sum_{\alpha \in A} \langle |T| e_{\alpha}, e_{\alpha} \rangle. \end{aligned}$$

Lemma: Let \mathcal{H} be a Hilbert space, and suppose $T \in \mathcal{B}(\mathcal{H})$. The following are equivalent:

- (i) $T \in L_1(\mathcal{B}(\mathcal{H}))$;
- (ii) $|T| \in L_1(\mathcal{B}(\mathcal{H}))$;
- (iii) $|T|^{1/2} \in L_2(\mathcal{B}(\mathcal{H}))$;
- (iv) there exists $S, R \in L_2(\mathcal{B}(\mathcal{H}))$ such that $T = SR$.

Proof. The statement (i) if and only if (iii) follows from definitions. The statement (i) if and only if (ii) follows from the fact that $\|T\| = \||T|\|$.

Now, to show (iii) implies (iv), we use the polar decomposition, $T = V|T|$. Notice that

$$\begin{aligned} T &= V|T| \\ &= \left(V|T|^{1/2} \right) |T|^{1/2}, \end{aligned}$$

where both factors are in $L_2(\mathcal{B}(\mathcal{H}))$. That the first factor is in $L_2(\mathcal{B}(\mathcal{H}))$ follows from the fact that $L_2(\mathcal{B}(\mathcal{H}))$ is a $*$ -ideal in $\mathcal{B}(\mathcal{H})$.

Now, if $T = SR$ with $S, R \in L_2(\mathcal{B}(\mathcal{H}))$, we let $T = V|T|$ be the polar decomposition of T , meaning $|T| = V^*T$. Then,

$$\begin{aligned} \|T\|_{\text{tr}} &= \sum_{\alpha} \langle |T| e_{\alpha}, e_{\alpha} \rangle \\ &= \sum_{\alpha} \langle V^* T e_{\alpha}, e_{\alpha} \rangle \\ &= \sum_{\alpha} \langle S R e_{\alpha}, V e_{\alpha} \rangle \end{aligned}$$

$$\begin{aligned}
&= \sum_{\alpha} \langle Re_{\alpha}, S^* Ve_{\alpha} \rangle \\
&= \langle R, S^* V \rangle_{\text{HS}} \\
&< \infty,
\end{aligned}$$

where we once again use the fact that $L_2(\mathbb{B}(\mathcal{H}))$ is a $*$ -ideal in $\mathbb{B}(\mathcal{H})$. \square

Lemma: Let \mathcal{H} be a Hilbert space. If $T \in L_1(\mathbb{B}(\mathcal{H}))$, and $(e_{\alpha})_{\alpha}$ is an orthonormal basis for \mathcal{H} , then

$$\sum_{\alpha \in A} \langle Te_{\alpha}, e_{\alpha} \rangle$$

is summable, and any choice of orthonormal basis yields the same result.

Proof. We know there are $S, R \in L_2(\mathbb{B}(\mathcal{H}))$ such that $T = SR$. Thus,

$$\begin{aligned}
\sum_{\alpha \in A} \langle Te_{\alpha}, e_{\alpha} \rangle &= \sum_{\alpha \in A} \langle Re_{\alpha}, S^* e_{\alpha} \rangle \\
&= \langle R, S^* \rangle_{\text{HS}}.
\end{aligned}$$

\square

Definition. Let \mathcal{H} be a Hilbert space. We define the trace as the map

$$\text{tr}(T) = \sum_{\alpha \in A} \langle Te_{\alpha}, e_{\alpha} \rangle,$$

where $(e_{\alpha})_{\alpha}$ is any orthonormal basis for \mathcal{H} .

Example. If $\theta_{x,y}$ is a rank-one operator, and $(e_{\alpha})_{\alpha}$ is an orthonormal basis, then

$$\begin{aligned}
\text{tr}(\theta_{x,y}) &= \sum_{\alpha \in A} \langle \theta_{x,y}(e_{\alpha}), e_{\alpha} \rangle \\
&= \sum_{\alpha \in A} \langle \langle e_{\alpha}, y \rangle x, e_{\alpha} \rangle \\
&= \sum_{\alpha \in A} \langle x, e_{\alpha} \rangle \langle e_{\alpha}, y \rangle \\
&= \langle x, y \rangle.
\end{aligned}$$

Proposition: The map $\text{tr}: L_1(\mathbb{B}(\mathcal{H})) \rightarrow \mathbb{C}$ is tracial, in that if

- (i) $R, S \in L_2(\mathbb{B}(\mathcal{H}))$, or
- (ii) $S \in L_1(\mathbb{B}(\mathcal{H}))$ and $R \in \mathbb{B}(\mathcal{H})$,

then

$$\text{tr}(RS) = \text{tr}(SR).$$

Proof.

- (1) Using the correspondence between trace and Hilbert–Schmidt inner product, we have

$$\begin{aligned}
\text{tr}(SR) &= \langle R, S^* \rangle_{\text{HS}} \\
&= \langle S, R^* \rangle_{\text{HS}} \\
&= \text{tr}(RS).
\end{aligned}$$

- (2) Letting $S = L_1(\mathbb{B}(\mathcal{H}))$, we may write $S = T_1 T_2$ as a product of Hilbert–Schmidt operators. Note that $T_2 R, R T_1 \in L_2(\mathbb{B}(\mathcal{H}))$ since Hilbert–Schmidt operators form a $*$ -ideal. Thus,

$$\begin{aligned}\mathrm{tr}(SR) &= \mathrm{tr}(T_1 T_2 R) \\ &= \mathrm{tr}(T_2 R T_1) \\ &= \mathrm{tr}(R T_1 T_2) \\ &= \mathrm{tr}(RS).\end{aligned}$$

□

Note that

$$\begin{aligned}\|T\|_{\mathrm{tr}} &= \mathrm{tr}(|T|) \\ \|T\|_{\mathrm{HS}} &= \mathrm{tr}(|T|^2)^{1/2} \\ \langle S, R \rangle_{\mathrm{HS}} &= \mathrm{tr}(R^* S) \\ &= \mathrm{tr}(SR^*).\end{aligned}$$

Theorem: Let \mathcal{H} be a Hilbert space.

- (1) The vector space $L_1(\mathbb{B}(\mathcal{H}))$ has the norm $\|\cdot\|_{\mathrm{tr}}$.
- (2) For $T \in L_1(\mathbb{B}(\mathcal{H}))$, we have $\|T\|_{\mathrm{op}} \leq \|T\|_{\mathrm{tr}}$ and $\|T^*\|_{\mathrm{tr}} = \|T\|_{\mathrm{tr}}$.
- (3) For $T \in \mathbb{B}(\mathcal{H})$ and $S \in L_1(\mathbb{B}(\mathcal{H}))$, we have

$$\begin{aligned}\|TS\|_{\mathrm{tr}} &\leq \|T\|_{\mathrm{op}} \|S\|_{\mathrm{tr}} \\ \|ST\|_{\mathrm{tr}} &\leq \|T\|_{\mathrm{op}} \|S\|_{\mathrm{tr}},\end{aligned}$$

so $L_1(\mathbb{B}(\mathcal{H}))$ is a two-sided $*$ -ideal in $\mathbb{B}(\mathcal{H})$.

- (4) The space $L_1(\mathbb{B}(\mathcal{H}))$ is complete when equipped with $\|\cdot\|_{\mathrm{tr}}$, making it a Banach $*$ -algebra.

Proof.

- (1) If $\|T\|_{\mathrm{tr}} = 0$, then $|T|^{1/2} = 0$ as $\|\cdot\|_{\mathrm{HS}}$ is a norm. Then, $|T| = 0$, so $T^*T = 0$, and $\|T\|_{\mathrm{op}}^2 = \|T^*T\|_{\mathrm{op}} = 0$, so $T = 0$.

Since $|\lambda T| = |\lambda| |T|$, we have

$$\begin{aligned}\|\lambda T\|_{\mathrm{tr}} &= \sum_{\alpha \in A} \langle |\lambda T| e_\alpha, e_\alpha \rangle \\ &= \sum_{\alpha \in A} \langle |\lambda| |T| e_\alpha, e_\alpha \rangle \\ &= |\lambda| \sum_{\alpha \in A} \langle |T| e_\alpha, e_\alpha \rangle \\ &= |\lambda| \|T\|_{\mathrm{tr}}.\end{aligned}$$

Now, suppose $T, S \in L_1(\mathbb{B}(\mathcal{H}))$, with polar decompositions $T = V|T|$ and $S = U|S|$, $(T + S) = W|T + S|$. Since $|T|^{1/2} \in L_2(\mathbb{B}(\mathcal{H}))$, we have

$$\begin{aligned}\|T + S\|_{\mathrm{tr}} &= \mathrm{tr}(|T + S|) \\ &= \mathrm{tr}(W^*(T + S)) \\ &= \mathrm{tr}(W^*T) + \mathrm{tr}(W^*S)\end{aligned}$$

$$\begin{aligned}
&= \operatorname{tr}(W^*V|T|) + \operatorname{tr}(W^*U|S|) \\
&= \operatorname{tr}(W^*V|T|^{1/2}|T|^{1/2}) + \operatorname{tr}(W^*U|S|^{1/2}|S|^{1/2}) \\
&= \langle |T|^{1/2}, |T|^{1/2}V^*W \rangle + \langle |S|^{1/2}, |S|^{1/2}U^*W \rangle \\
&\leq \| |T|^{1/2} \|_{\text{HS}} \| |T|^{1/2}V^*W \|_{\text{HS}} + \| |S|^{1/2} \|_{\text{HS}} \| |S|^{1/2}U^*W \|_{\text{HS}} \\
&\leq \| |T|^{1/2} \|_{\text{HS}} \| |T|^{1/2} \|_{\text{HS}} \| V^*W \|_{\text{op}} + \| |S|^{1/2} \|_{\text{HS}} \| |S|^{1/2} \|_{\text{HS}} \| U^*W \|_{\text{op}} \\
&\leq \| |T|^{1/2} \|_{\text{HS}}^2 + \| |S|^{1/2} \|_{\text{HS}}^2 \\
&= \|T\|_{\text{tr}} + \|S\|_{\text{tr}}.
\end{aligned}$$

(2) Let T be a trace-class operator on \mathcal{H} . Using the fact that $|T|$ is positive, we have

$$\begin{aligned}
\|T\|_{\text{tr}} &= \| |T|^{1/2} \|_{\text{HS}}^2 \\
&\geq \| |T|^{1/2} \|_{\text{op}}^2 \\
&= \| |T| \|_{\text{op}} \\
&= \|T\|_{\text{op}}.
\end{aligned}$$

Now, applying the polar decomposition to T to obtain the partial isometry $V \in \mathcal{B}(\mathcal{H})$ with $T = V|T|$, we have

$$\begin{aligned}
\|T^*\|_{\text{tr}} &= \operatorname{tr}(|T^*|) \\
&= \operatorname{tr}(V|T|V^*) \\
&= \operatorname{tr}(TV^*) \\
&= \operatorname{tr}(V^*T) \\
&= \operatorname{tr}(|T|) \\
&= \|T\|_{\text{tr}}.
\end{aligned}$$

(3) We have

$$\begin{aligned}
\|TS\|_{\text{tr}} &= \sum_{\alpha \in A} \langle |TS|e_\alpha, e_\alpha \rangle \\
&\leq \sum_{\alpha \in A} \left(\|T\|_{\text{op}} |S|e_\alpha, e_\alpha \right) \\
&= \|T\|_{\text{op}} \sum_{\alpha \in A} \langle |S|e_\alpha, e_\alpha \rangle \\
&= \|T\|_{\text{op}} \|S\|_{\text{tr}}.
\end{aligned}$$

Similarly to the case of Hilbert–Schmidt operators, we have

$$\begin{aligned}
\|ST\|_{\text{tr}} &= \|(ST)^*\|_{\text{tr}} \\
&= \|T^*S^*\|_{\text{tr}} \\
&\leq \|T^*\|_{\text{op}} \|S^*\|_{\text{tr}} \\
&= \|T\|_{\text{op}} \|S\|_{\text{tr}}.
\end{aligned}$$

(4) Let $(T_n)_n$ be a $\|\cdot\|_{\text{tr}}$ -Cauchy sequence in $L_1(\mathcal{B}(\mathcal{H}))$. Let $C > 0$ be such that $\|T_n\|_{\text{tr}} \leq C$ for all n . By (2), $(T_n)_n$ is $\|\cdot\|_{\text{op}}$ -Cauchy, so there is $T \in \mathcal{B}(\mathcal{H})$ such that $\|T_n - T\|_{\text{op}} \rightarrow 0$.

We claim that T is trace-class. Let $(e_\alpha)_\alpha$ be an orthonormal basis for \mathcal{H} , and suppose $F \subseteq A$ is finite. We see that $(|T_n|)_n \rightarrow |T|$ in operator norm, so that

$$\begin{aligned} \sum_{\alpha \in F} \langle |T| e_\alpha, e_\alpha \rangle &= \lim_{n \rightarrow \infty} \left(\sum_{\alpha \in F} \langle |T_n| e_\alpha, e_\alpha \rangle \right) \\ &\leq \limsup_{n \rightarrow \infty} \|T_n\|_{\text{tr}} \\ &\leq C. \end{aligned}$$

Taking the supremum over all finite $F \subseteq A$, we have $\|T\|_{\text{tr}} \leq C < \infty$.

Now, we claim that $\|T - T_n\|_{\text{tr}} \rightarrow 0$. Letting $\varepsilon > 0$, we find $N \in \mathbb{N}$ such that for $m, n \geq N$, $\|T_m - T_n\|_{\text{tr}} < \varepsilon$. We find that $(|T_m - T - n|)_m \rightarrow |T - T_n|$ in operator norm as $m \rightarrow \infty$ with fixed n . Thus, if $F \subseteq A$ is finite, for all $n \geq N$, we have

$$\begin{aligned} \sum_{\alpha \in F} \langle |T - T_n| e_\alpha, e_\alpha \rangle &= \lim_{m \rightarrow \infty} \left(\sum_{\alpha \in F} \langle |T_m - T_n| e_\alpha, e_\alpha \rangle \right) \\ &\leq \limsup_{m \rightarrow \infty} \|T_m - T_n\|_{\text{tr}} \\ &\leq \varepsilon. \end{aligned}$$

Taking the supremum over all finite subsets $F \subseteq A$, we have $\|T - T_n\|_{\text{tr}} \leq \varepsilon$ for all $n \geq N$.

□

Proposition: Let \mathcal{H} be a Hilbert space. The following inclusions hold.

$$\mathbb{F}(\mathcal{H}) \subseteq L_1(\mathbb{B}(\mathcal{H})) \subseteq L_2(\mathbb{B}(\mathcal{H})) \subseteq \mathbb{B}(\mathcal{H}).$$

Moreover, $\overline{\mathbb{F}(\mathcal{H})}^{\|\cdot\|_{\text{tr}}} = L_1(\mathbb{B}(\mathcal{H}))$.

Proof. Note that $L_2(\mathbb{B}(\mathcal{H}))$ is an ideal, so that $L_1(\mathbb{B}(\mathcal{H})) \subseteq L_2(\mathbb{B}(\mathcal{H}))$.

We have shown that every rank-one operator $\xi \otimes \bar{\eta}$ is trace-class, so $\mathbb{F}(\mathcal{H}) \subseteq L_1(\mathbb{B}(\mathcal{H}))$.

Let $T \in L_1(\mathbb{B}(\mathcal{H}))$, and let $\varepsilon > 0$. Then, there is an orthonormal basis $(e_\alpha)_\alpha$ and a finite subset $F \subseteq A$ such that

$$\sum_{\alpha \notin F} \langle |T| e_\alpha, e_\alpha \rangle < \varepsilon.$$

Now, let P be the projection onto $\text{span}(\{e_\alpha \mid \alpha \in F\})$, and let $T - TP = V|T - TP|$ be the polar decomposition, so $V^*(T - TP) = |T - TP|$. Thus, we have

$$\begin{aligned} \|T - TP\|_{\text{tr}} &= \sum_{\alpha \in A} \langle |T - TP| e_\alpha, e_\alpha \rangle \\ &= \sum_{\alpha \in A} \langle (T - TP)e_\alpha, Ve_\alpha \rangle \\ &= \sum_{\alpha \in F} \langle (T - TP)e_\alpha, Ve_\alpha \rangle + \sum_{\alpha \notin F} \langle (T - TP)e_\alpha, e_\alpha \rangle \\ &= \sum_{\alpha \notin F} \langle Te_\alpha, Ve_\alpha \rangle \\ &= \sum_{\alpha \notin F} \langle |T| e_\alpha, e_\alpha \rangle \end{aligned}$$

$$< \varepsilon.$$

Since \mathcal{TP} is of finite rank, and the trace class operators are complete, we have $\overline{\mathbb{F}(\mathcal{H})}^{\|\cdot\|_{\text{tr}}} = \mathcal{L}_1(\mathbb{B}(\mathcal{H}))$. \square

Proposition: Let \mathcal{H} be a Hilbert space. The trace, $\text{tr}: \mathcal{L}_1(\mathbb{B}(\mathcal{H})) \rightarrow \mathbb{C}$ is a contractive, positive, and faithful linear functional, with

$$|\text{tr}(ST)| \leq \|S\|_{\text{op}} \|T\|_{\text{tr}}$$

for all $S \in \mathbb{B}(\mathcal{H})$ and $T \in \mathcal{L}_1(\mathbb{B}(\mathcal{H}))$.

Proof. Linearity is clear by definition, and the fact that the trace is a contraction follows from taking $S = I_{\mathcal{H}}$.

Note that

$$\begin{aligned} \text{tr}(T^*T) &= \langle T, T \rangle_{\text{HS}} \\ &= \|T\|_{\text{HS}}^2 \\ &\geq 0, \end{aligned}$$

so $\text{tr}(T^*T) = 0$ implies $T = 0$, meaning that it is faithful.

Now, let $T \in \mathcal{L}_1(\mathbb{B}(\mathcal{H}))$ have the polar decomposition $T = V|T|$. Using the Cauchy–Schwarz inequality for $\langle \cdot, \cdot \rangle_{\text{HS}}$ along with some other properties, we have

$$\begin{aligned} |\text{tr}(ST)| &= \left| \text{tr}\left(SV|T|^{1/2}|T|^{1/2}\right) \right| \\ &= \left| \left\langle |T|^{1/2}V^*S^*, |T|^{1/2} \right\rangle_{\text{HS}} \right| \\ &\leq \left\| |T|^{1/2}V^*S^* \right\|_{\text{HS}} \left\| |T|^{1/2} \right\|_{\text{HS}} \\ &\leq \left\| |T|^{1/2} \right\|_{\text{HS}} \left\| |T|^{1/2} \right\|_{\text{HS}} \|V^*S^*\|_{\text{op}} \\ &\leq \left\| |T|^{1/2} \right\|_{\text{HS}}^2 \|S^*\|_{\text{op}} \\ &= \|T\|_{\text{tr}} \|S\|_{\text{op}}. \end{aligned}$$

\square

Example. Let $T \in \mathbb{F}(\mathcal{H})$ be a finite-rank operator. We may compute the trace-class norm of T by looking at the singular values,

$$T = \sum_{k=1}^n \mu_k \theta_{f_k, e_k},$$

where $|T| = \sum_{k=1}^n \mu_k \theta_{e_k, e_k}$ is the diagonalization of the positive finite-rank operator $|T|$.

Since the trace is linear, we calculate

$$\begin{aligned} \|T\|_{\text{tr}} &= \text{tr}(|T|) \\ &= \text{tr}\left(\sum_{k=1}^n \mu_k \theta_{e_k, e_k}\right) \\ &= \sum_{k=1}^n \mu_k \text{tr}(\theta_{e_k, e_k}) \\ &= \sum_{k=1}^n \mu_k. \end{aligned}$$

Now, similar to the case of the compact and Hilbert–Schmidt operators, where we realize them as tensor products of $\mathcal{H} \otimes \overline{\mathcal{H}}$ with respect to the injective norm and 2-norm respectively, we may realize the trace-class operators as a tensor product.

Proposition: Let \mathcal{H} be a Hilbert space. Then, there is an isometric isomorphism

$$T: \mathcal{H} \hat{\otimes} \overline{\mathcal{H}},$$

given by $x \otimes \bar{y} \mapsto \theta_{x,y}$.

Proof. We have established a linear isomorphism that maps $x \otimes \bar{y} \mapsto \theta_{x,y}$ between $\mathcal{H} \otimes \overline{\mathcal{H}}$ and $\mathbb{F}(\mathcal{H})$.

Now, let $t \in \mathcal{H} \otimes \overline{\mathcal{H}}$. Then, for any representation $t = \sum_{k=1}^n x_k \otimes \bar{y}_k$, we obtain

$$\begin{aligned} \|T(t)\|_{\text{tr}} &= \left\| \sum_{k=1}^n \theta_{x_k, y_k} \right\|_{\text{tr}} \\ &\leq \sum_{k=1}^n \|\theta_{x_k, y_k}\|_{\text{tr}} \\ &= \sum_{k=1}^n \|x_k\| \|y_k\|. \end{aligned}$$

Taking the infimum over representations, we get $\|T(t)\|_{\text{tr}} \leq \|t\|_{\wedge}$.

On the other hand, using the singular value decomposition, we may express

$$T(t) = \sum_{k=1}^n \mu_k \theta_{f_k, e_k},$$

where $\mu_k > 0$ are nonzero eigenvalues for $|T(t)|$ and $(e_k)_{k=1}^n$ and $(f_k)_{k=1}^n$ are orthonormal families. This gives

$$\begin{aligned} \|t\|_{\wedge} &= \left\| \sum_{k=1}^n \mu_k (f_k \otimes \bar{e}_k) \right\|_{\wedge} \\ &\leq \sum_{j=1}^n \|\mu_k f_k\| \|e_k\| \\ &= \sum_{k=1}^n \mu_k \\ &= \|T(t)\|_{\text{tr}}, \end{aligned}$$

so T is an isometry when $\mathcal{H} \otimes \overline{\mathcal{H}}$ is equipped with the projective norm and $\mathbb{F}(\mathcal{H})$ with the trace-class norm. By continuity, we have the isometric isomorphism $T: \mathcal{H} \hat{\otimes} \overline{\mathcal{H}} \rightarrow L_1(\mathbb{B}(\mathcal{H}))$. \square

Interlude: Tensor Products of Operators

Recall that if \mathcal{H} and \mathcal{K} are Hilbert spaces, the Hilbert space tensor product $\mathcal{H} \otimes \mathcal{K}$ is endowed with the norm induced by the inner product

$$\langle x \otimes y, x' \otimes y' \rangle = \langle x, x' \rangle \langle y, y' \rangle.$$

We usually call this the 2-norm.

Proposition: Let \mathcal{H} and \mathcal{K} be Hilbert spaces, and suppose $T \in \mathcal{B}(\mathcal{H})$ and $S \in \mathcal{B}(\mathcal{K})$. The linear map $T \otimes S: \mathcal{H} \otimes \mathcal{K} \rightarrow \mathcal{H} \otimes \mathcal{K}$, given by $(T \otimes S)(x \otimes y) = Tx \otimes Sy$, is bounded with respect to the 2-norm. The continuous extension, $T \otimes S \in \mathcal{B}(\mathcal{H} \otimes \mathcal{K})$, has the cross norm $\|T \otimes S\|_{\text{op}} = \|T\|_{\text{op}} \|S\|_{\text{op}}$.

Proof. Consider the linear map $T \otimes I: \mathcal{H} \otimes \mathcal{K} \rightarrow \mathcal{H} \otimes \mathcal{K}$, where $T \otimes I(h \otimes k) = Th \otimes k$ for $h \in \mathcal{H}$ and $k \in \mathcal{K}$.

We will show that $T \otimes I$ is bounded. Let $t = \sum_{j=1}^n h_j \otimes k_j \in \mathcal{H} \otimes \mathcal{K}$, and regard $\{k_1, \dots, k_n\}$ as orthonormal. Then, the families $\{Th_j \otimes k_j\}_{j=1}^n$ and $\{h_j \otimes k_j\}_{j=1}^n$ are orthogonal. Using the Pythagorean theorem and the cross norm on $\mathcal{H} \otimes \mathcal{K}$, we get

$$\begin{aligned} \|(T \otimes I)(t)\|^2 &= \left\| \sum_{j=1}^n Th_j \otimes k_j \right\|^2 \\ &= \sum_{j=1}^n \|Th_j \otimes k_j\|^2 \\ &= \sum_{j=1}^n \|Th_j\|^2 \|k_j\|^2 \\ &\leq \sum_{j=1}^n \|T\|_{\text{op}}^2 \|h_j\|^2 \|k_j\|^2 \\ &= \|T\|_{\text{op}}^2 \sum_{j=1}^n \|h_j\|^2 \|k_j\|^2 \\ &= \|T\|_{\text{op}}^2 \sum_{j=1}^n \|h_j \otimes k_j\|^2 \\ &= \|T\|_{\text{op}}^2 \left\| \sum_{j=1}^n h_j \otimes k_j \right\|^2 \\ &= \|T\|_{\text{op}}^2 \|t\|^2. \end{aligned}$$

Thus, $T \otimes I$ is bounded, with $\|T \otimes I\|_{\text{op}} \leq \|T\|_{\text{op}}$, and similarly with $I \otimes S$. Note that $T \otimes S = (T \otimes I) \circ (I \otimes S)$, so $T \otimes S$ is bounded with

$$\begin{aligned} \|T \otimes S\|_{\text{op}} &\leq \|T \otimes I\|_{\text{op}} \|I \otimes S\|_{\text{op}} \\ &\leq \|T\|_{\text{op}} \|S\|_{\text{op}}. \end{aligned}$$

Moreover,

$$\begin{aligned} \|T \otimes S\|_{\text{op}} &\geq \sup_{\substack{x \in B_{\mathcal{H}} \\ y \in B_{\mathcal{K}}}} \|(T \otimes S)(x \otimes y)\| \\ &= \sup_{\substack{x \in B_{\mathcal{H}} \\ y \in B_{\mathcal{K}}}} \|Tx \otimes Sy\| \\ &= \sup_{x \in B_{\mathcal{H}}} \|Tx\| \sup_{y \in B_{\mathcal{K}}} \|Sy\| \\ &= \|T\|_{\text{op}} \|S\|_{\text{op}}, \end{aligned}$$

so $\|T \otimes S\|_{\text{op}} = \|T\|_{\text{op}} \|S\|_{\text{op}}$. Thus, $T \otimes S$ extends continuously to a bounded operator $T \otimes S \in \mathcal{B}(\mathcal{H} \otimes \mathcal{K})$. \square

The traditional rules of tensor calculus extend to operators.

Lemma: Let \mathcal{H} and \mathcal{K} be Hilbert spaces. Suppose $T, T_1, T_2 \in \mathcal{B}(\mathcal{H})$, and $S, S_1, S_2 \in \mathcal{B}(\mathcal{K})$, with $\alpha \in \mathbb{C}$. Then,

- (1) $(T_1 + \alpha T_2) \otimes S = T_1 \otimes S + \alpha(T_2 \otimes S)$;
- (2) $T \otimes (S_1 + \alpha S_2) = T \otimes S_1 + \alpha(T \otimes S_2)$;
- (3) $(T_1 \otimes S_1)(T_2 \otimes S_2) = T_1 T_2 \otimes S_1 S_2$;
- (4) $(T \otimes S)^* = T^* \otimes S^*$.

Proposition: Let \mathcal{H} and \mathcal{K} be Hilbert spaces. There is an injective $*$ -homomorphism $\iota: \mathbb{B}(\mathcal{H}) \otimes \mathbb{B}(\mathcal{K}) \hookrightarrow \mathbb{B}(\mathcal{H} \otimes \mathcal{K})$.

Proof. The map $(T, S) \mapsto T \otimes S$ is bilinear, so we have a linear map ι via the universal property of tensor products. The fact that ι is injective follows from dropping the analytic structure of $\mathbb{B}(\mathcal{H})$ and $\mathbb{B}(\mathcal{K})$. \square

Proposition: Let \mathcal{H} be a Hilbert space, Γ a set, and let $T \in \mathbb{B}(\mathcal{H})$. Then, the amplification

$$\bigoplus_{t \in \Gamma} T \in \mathbb{B}\left(\bigoplus_{t \in \Gamma} \mathcal{H}\right)$$

is unitarily equivalent to $T \otimes I$ in $\mathbb{B}(\mathcal{H} \otimes \ell_2(\Gamma))$, where $\mathcal{H} \otimes \ell_2(\Gamma)$ is endowed with the 2-norm.

Proof. We know there is a unitary operator $U: \mathcal{H} \otimes \ell_2(\Gamma) \rightarrow \bigoplus_{t \in \Gamma} \mathcal{H}$ that satisfies $U(\xi \otimes f) = (f(t)\xi)_{t \in \Gamma}$.

We claim that $U^*\left(\bigoplus_{t \in \Gamma} T\right)U = T \otimes I$, or equivalently, $\left(\bigoplus_{t \in \Gamma} T\right)U = U(T \otimes I)$.

For an elementary tensor $\xi \otimes f \in \mathcal{H} \otimes \ell_2(\Gamma)$, we have

$$\begin{aligned} \left(\bigoplus_{t \in \Gamma} T\right)U(\xi \otimes f) &= \left(\bigoplus_{t \in \Gamma} T\right)(f(t)\xi)_{t \in \Gamma} \\ &= (f(t)T\xi)_{t \in \Gamma}. \end{aligned}$$

Meanwhile, we have

$$\begin{aligned} U(T \otimes I)(\xi \otimes f) &= U(T\xi \otimes f) \\ &= (f(t)T\xi)_{t \in \Gamma}. \end{aligned}$$

Now, since $\left(\bigoplus_{t \in \Gamma} T\right)U$ and $U(T \otimes I)$ agree on simple tensors, so they agree on $\mathcal{H} \otimes \ell_2(\Gamma)$ by linearity and continuity. \square

Now, we may introduce two more locally convex topologies on $\mathbb{B}(\mathcal{H})$, the σ -weak and σ -strong (or ultra-weak and ultrastrong) topologies.

Duality and the Weak* Topology

Nuclear Maps

Now, we will use results related to completely positive maps to understand nuclearity in C^* -algebras.

Definition. Let $\theta: A \rightarrow B$ be a map between C^* -algebras. We say θ is nuclear if there exist completely positive contractions $\varphi_n: A \rightarrow \text{Mat}_{k(n)}(\mathbb{C})$ and $\psi_n: \text{Mat}_{k(n)}(\mathbb{C}) \rightarrow B$ such that

$$\|\psi_n \circ \varphi_n(a) - \theta(a)\| \rightarrow 0$$

for all $a \in A$.

There is a similar definition for von Neumann algebras.

Definition. If A is a C^* -algebra, and N is a von Neumann algebra, a map $\theta: A \rightarrow N$ is called weakly nuclear if there exist completely positive contractions $\varphi_n: A \rightarrow \text{Mat}_{k(n)}(\mathbb{C})$ and $\psi_n: \text{Mat}_{k(n)}(\mathbb{C}) \rightarrow N$ such that, for all $\eta \in N_*$, where N_* is the predual of N , we have

$$\eta(\psi_n \circ \varphi_n(a)) \rightarrow \eta(\theta(a)).$$

We call convergence in the weak* topology induced by the predual of N *point-ultraweak* convergence.

Recall that when we are checking convergence of bounded nets, we have $\psi_n \circ \varphi_n \xrightarrow{\text{BW}} \theta$, if and only if

$$\langle \psi_n \circ \varphi_n(a)v, w \rangle \rightarrow \langle \theta(a)v, w \rangle$$

for all $a \in A$ and $v, w \in \Omega \subseteq \mathcal{H}$.

What makes nuclearity interesting is that it is dependent on the range. For instance, there are von Neumann algebras for which the identity map is not nuclear, while the natural inclusion is always nuclear.

Proposition: Let $M \subseteq \mathcal{B}(\mathcal{H})$ be a von Neumann algebra. The natural inclusion map, $M \hookrightarrow \mathcal{B}(\mathcal{H})$ is always weakly nuclear.

Proof. Let $\{P_i\}_{i \in I}$ be a net of finite rank projections increasing to the identity. That is, if $i \leq j$, then $P_i \leq P_j$, and also $\|P_i v - v\| \rightarrow 0$ for all $v \in \mathcal{H}$.

Now, if P_i has rank $k(i)$, we define the completely positive contractions $\varphi_i: M \rightarrow \text{Mat}_{k(i)}(\mathbb{C})$ via the identification $\text{Mat}_{k(i)}(\mathbb{C}) \cong P_i \mathcal{B}(\mathcal{H}) P_i$ with the compression $\varphi_i(T) = P_i T P_i$.

Let $\psi_i: \text{Mat}_{k(i)}(\mathbb{C}) \rightarrow \mathcal{B}(\mathcal{H})$ be the natural inclusion map — i.e., $\varphi_i(T) = P_i T P_i$ as the matrix representation $(T_{ij})_{ij}$, and $\psi_i((T_{ij})_{ij}) = P_i T P_i$, where T is the operator for the matrix $(T_{ij})_{ij}$.

Now, since the predual of $\mathcal{B}(\mathcal{H})$ is the trace class operators, and the $(P_i)_i$ converge in the to the identity, the net $(\psi_i \circ \varphi_i)_i$ converges pointwise (i.e., ultraweakly) to the identity. \square

Exercise (Exercise 2.1.1): Show that $\theta: A \rightarrow B$ is nuclear if and only if for each finite subset $F \subseteq A$ and $\varepsilon > 0$, there exist $n \in \mathbb{N}$ and completely positive contractions $\varphi: A \rightarrow \text{Mat}_n(\mathbb{C})$, $\psi: \text{Mat}_n(\mathbb{C}) \rightarrow B$ such that $\|\theta(a) - \psi \circ \varphi(a)\| < \varepsilon$ for all $a \in F$.

Solution: If $\theta: A \rightarrow B$ is nuclear, then we have nets $\varphi_i: A \rightarrow \text{Mat}_{n(i)}(\mathbb{C})$ and $\psi_i: \text{Mat}_{n(i)}(\mathbb{C}) \rightarrow B$ such that $\|\theta(a) - \psi_i \circ \varphi_i(a)\| \rightarrow 0$ as a net. Therefore, for any $\varepsilon > 0$, there is some i such that for all $i > I$ we may find some finite subset F such that $a \in F$ and $\|\theta(a) - \psi_i \circ \varphi_i(a)\| < \varepsilon$. The value $n(i)$ is thus our desired value of n .

Let \mathcal{F} be the set

$$\mathcal{F} = \{(F, \varepsilon) \mid F \subseteq A \text{ is finite, } \varepsilon > 0\},$$

directed by

$$(F, \varepsilon) \leq (F', \varepsilon') \text{ if and only if } F \subseteq F' \text{ and } \varepsilon' < \varepsilon.$$

Suppose θ satisfies the condition of the theorem. We define the net of completely positive contractions with respect to \mathcal{F} to be $\varphi_{(F, \varepsilon)}: A \rightarrow \text{Mat}_{n(F, \varepsilon)}(\mathbb{C})$ and $\psi_{(F, \varepsilon)}: \text{Mat}_{n(F, \varepsilon)}(\mathbb{C}) \rightarrow B$. Then, we have

$$\|\theta(a) - \psi_{n(F, \varepsilon)} \circ \varphi_{n(F, \varepsilon)}(a)\| \rightarrow 0,$$

so that θ is nuclear.

Exercise (Exercise 2.1.2): Prove that $\theta: A \rightarrow B$ is nuclear if and only if there exist completely positive contractions $\varphi_n: A \rightarrow C_n$ and $\psi_n: C_n \rightarrow B$, where the C_n are finite-dimensional C^* -algebras.

Exercise (Exercise 2.1.3): If $\theta: A \rightarrow B$ is nuclear and $C \subseteq A$ is a C^* -algebra, then $\theta|_C: C \rightarrow B$ is also nuclear.

Exercise (Exercise 2.1.4): If $\theta: A \rightarrow B$ and $\sigma: B \rightarrow C$ are completely positive contractions such that either θ or σ is nuclear, then so is $\sigma \circ \theta$.

Exercise (Exercise 2.1.5): If A is a C^* -algebra such that the identity map on A is nuclear, then any other completely positive contraction $\theta: A \rightarrow B$ is also nuclear.

Exercise (Exercise 2.1.6): Assume $A \subseteq \mathcal{B}(\mathcal{H})$ is a concretely represented C^* -algebra such that the inclusion map $A \hookrightarrow \mathcal{B}(\mathcal{H})$ is nuclear. Show that if $\theta: A \rightarrow \mathcal{B}(\mathcal{K})$ is any completely positive contraction, then θ is nuclear.

Exercise (Exercise 2.1.7): If $\theta: A \rightarrow B$ is nuclear, and $C \subseteq B$ is a C^* -subalgebra with the properties that

- (a) $\theta(A) \subseteq C$; and
- (b) there exists a conditional expectation $\Phi: B \rightarrow C$,

then $\theta: A \rightarrow C$ is nuclear.

Exercise (Exercise 2.1.8): If $\theta: A \rightarrow B$ and $C \subseteq B$ is a C^* -subalgebra with properties that

- (a) $\theta(A) \subseteq C$; and
- (b) there exist a sequence of completely positive contractions $\Phi_n: B \rightarrow C$ such that $\Phi_n|_C \rightarrow \text{id}_C$ in the point-norm topology,

then $\theta: A \rightarrow C$ is nuclear.

Definition. If A is a unital C^* -algebra, an extension is called locally split if, for each finite-dimensional operator system $E \subseteq A/J$, there exists a unital completely positive map $\sigma: E \rightarrow A$ such that $\pi \circ \sigma = \text{id}_E$.

$$0 \longrightarrow J \longrightarrow A \xrightarrow{\pi} A/J \longrightarrow 0$$

Exercise (Exercise 2.1.9): Let $\theta: A \rightarrow B$ be a unital nuclear map, such that $\theta|_J = 0$ for some ideal $J \subseteq A$. Show that θ descends to a unital completely positive map $\hat{\theta}: A/J \rightarrow B$.

Next, show that if the extension is locally split, then $\hat{\theta}$ is nuclear.

$$0 \longrightarrow J \longrightarrow A \xrightarrow{\pi} A/J \longrightarrow 0$$

Amenability with C^* -Algebras
