

Basic Structure of von Neumann Algebras

We start by recalling some of the topologies on $B(H)$.

Definition: Let H be a Hilbert space, with $B(H)$ denoting the space of bounded operators on H .

The *strong operator topology*, or SOT, is the locally convex topology generated by the seminorms

$$\{\|Tv\| \mid T \in B(H), v \in H\}$$

The *weak operator topology*, or WOT, is the locally convex topology generated by the seminorms

$$\{|\langle Tv, w \rangle| \mid T \in B(H), v, w \in H\}$$

Theorem: Let $\phi: B(H) \rightarrow \mathbb{C}$ be a linear functional. The following are equivalent:

- (i) there are $\xi_k, \eta_k \in H$ such that $\phi(T) = \sum_{k=1}^n \langle T\xi_k, \eta_k \rangle$;
- (ii) ϕ is WOT-continuous;
- (iii) ϕ is SOT-continuous.

Proof. The directions (i) implies (ii) implies (iii) are pretty much by definition. To see (iii) implies (i), we have ξ_1, \dots, ξ_n such that, for all $T \in B(H)$, $\max \|T\xi_k\| \leq 1$ implies $\phi(T) \leq 1$. Then, we have

$$|\phi(T)| \leq \left(\sum_{k=1}^n \|T\xi_k\|^2 \right)^{1/2}.$$

Let

$$\begin{aligned} H^{(n)} &:= \bigoplus_{k=1}^n H \\ T^{(n)} &:= \text{diag}(T, \dots, T) \in B(H^{(n)}), \end{aligned}$$

and let $\xi = (\xi_1, \dots, \xi_n) \in H^{(n)}$. We see then that the linear functional $\psi: H \rightarrow \mathbb{C}$ given by

$$\psi(T^{(n)}\xi) = \phi(T)$$

defines a linear functional on the closed subspace of K spanned by the vectors

$$\{T^{(n)}\xi \mid T \in B(H)\},$$

and has

$$|\psi(T^{(n)}\xi)| \leq \|T^{(n)}\xi\|,$$

so by the Riesz Representation Theorem for Hilbert Spaces, it follows there is $\eta = (\eta_1, \dots, \eta_n)$ such that

$$\begin{aligned} \phi(x) &= \langle T^{(n)}\xi, \eta \rangle \\ &= \sum_{k=1}^n \langle T\xi_k, \eta_k \rangle. \end{aligned}$$

□

Corollary: Every SOT-closed convex subset of $B(H)$ is WOT-closed.

Proof. The closed convex subsets of a locally convex topological vector space are determined by the continuous linear functionals, as follows from an application of the Hahn–Banach separation. \square

Theorem: The unit ball of $B(H)$ is WOT-compact.

Proof. Let $\overline{\mathbb{D}}$ denote the closed unit disk of \mathbb{C} , and consider the set

$$K = \prod_{x,y \in B_H} \overline{\mathbb{D}}.$$

This space is compact by Tychonoff's theorem. Define the embedding $\phi: B_{B(H)} \rightarrow K$ given by

$$\phi(T) = (\langle Tx, y \rangle)_{x,y}.$$

By Cauchy–Schwarz, we have

$$\begin{aligned} |\langle Tx, y \rangle| &\leq \|T\|_{\text{op}} \|x\| \|y\| \\ &\leq 1, \end{aligned}$$

so ϕ is well-defined. We see that ϕ is WOT-continuous by definition and injective, so we only need to show that $\text{im}(\phi)$ is closed. Let $(T_i)_i \subseteq B_{B(H)}$ be a net with

$$\lim_{i \in I} (\langle T_i x, y \rangle)_{x,y} = (z_{x,y})_{x,y}.$$

We have that $(z_{x,y})_{x,y} \in K$ since K is compact, and since the product topology is the topology of pointwise convergence, we have

$$\lim_{i \in I} \langle T_i x, y \rangle = z_{x,y}$$

defines a sesquilinear form $F(x, y)$. This means we may find $T \in B_{B(H)}$ such that $F(x, y) = \langle Tx, y \rangle$, and so $(T_i)_i \rightarrow T$ in WOT. \square

Definition: A *partial isometry* is an operator $W \in B(H)$ such that for any $h \in (\ker(W))^\perp$, we have $\|Wh\| = \|h\|$. The space $(\ker(W))^\perp$ is called the *initial space* of W , and the space $\text{im}(W)$ is called the *final space* of W .

Proposition: If $W \in B(H)$, the following are equivalent:

- (i) W is a partial isometry;
- (ii) W^* is a partial isometry;
- (iii) W^*W is a projection (onto the initial space of W);
- (iv) WW^* is a projection (onto the final space of W);

Proof. Let W be a partial isometry, meaning that W is an isometry from $(\ker(W))^\perp$ to $\text{im}(W)$. Since $\text{im}(W)$ is dense in $(\ker(W^*))^\perp$, it follows that we only need to show that W^* is an isometry on $\text{im}(W)$. Let $k \in \text{im}(W)$, so there is $h \in (\ker(W))^\perp$ such that $Wh = k$. Then, we have

$$\langle Wh, Wh \rangle = \langle h, h \rangle$$

so

$$\langle W^*Wh - h, h \rangle = 0,$$

meaning that $W^*W - I$ is zero on $(\ker(W))^\perp$, so we have

$$\begin{aligned} \|W^*k\| &= \|W^*Wh\| \\ &= \|h\| \end{aligned}$$

$$\begin{aligned} &= \|Wh\| \\ &= \|k\|, \end{aligned}$$

meaning W^* is a partial isometry.

By taking adjoints, we see that (i) and (ii) are equivalent. Let $x \in H$ have the decomposition $x = y + z$ where $y \in \ker(W)$ and $z \in (\ker(W))^\perp$. We will show that $W^*Wx = z$. Observe that $Wx = Wz$, meaning that

$$\begin{aligned} \langle z - W^*Wx, z \rangle &= \langle z - W^*Wz, z \rangle \\ &= \langle z, z \rangle - \langle W^*Wz, z \rangle \\ &= \langle z, z \rangle - \langle Wz, Wz \rangle \\ &= 0, \end{aligned}$$

since $\|Wz\| = \|z\|$ by definition. In particular, following from the polarization identity, this means that for all $v \in H$, we have $\langle z - W^*Wx, v \rangle = 0$, so that $z = W^*Wx$. This shows that (i) implies (iii). By replacing all instances of W with W^* , we see that (ii) implies that WW^* is a projection onto the initial space of W^* , which is equal to the final space of W . \square

Theorem (Polar Decomposition): Let $A \in B(H)$. Then, there is a partial isometry W with initial space $(\ker(A))^\perp$ and final space $\overline{\text{im}(A)}$ such that $A = W|A|$. Moreover, if $A = UP$, where P is a positive operator and U is a partial isometry with $\ker(U) = \ker(P)$, then $P = |A|$ and $U = W$.

Proof. Let $h \in H$. Then,

$$\begin{aligned} \|Ah\| &= \langle A^*Ah, h \rangle \\ &= \langle |A|h, |A|h \rangle, \end{aligned}$$

so that

$$\|Ah\| = \||A|h\|.$$

We may thus define $W: \text{im}(|A|) \rightarrow \overline{\text{im}(A)}$ by taking

$$W(|A|h) = Ah.$$

Then, from above, we know that W is an isometry, so it can be extended to an isometry from $\overline{\text{im}(|A|)}$ to $\overline{\text{im}(A)}$. We may then extend W to all of H by defining it to be 0 on $(\text{im}(|A|))^\perp$. This makes W a partial isometry with $W|A| = A$. We must verify that W has the correct initial space. That is, we must show that $\overline{\text{im}(|A|)} = (\ker(A))^\perp$.

Suppose $f = A^*g$ for some $g \in (\ker(A^*))^\perp = \overline{\text{im}(A)}$. Then, $\text{im}(A^*A)$ is dense in $(\ker(A))^\perp$. Yet, since $A^*Ak = |A|h$, where $h = |A|k$, it follows that $\text{im}(|A|)$ is dense in $(\ker(A))^\perp$.

For uniqueness, we have that $A^*A = PU^*UP$, but since U^*U is the projection onto the initial space, it follows that $(\ker(U))^\perp = (\ker(P))^\perp = \overline{\text{im}(P)}$, meaning $A^*A = P^2$, so $P = |A|$ by the uniqueness in the continuous functional calculus. For any $h \in H$, we have $W|A|h = Ah = U|A|h$, meaning that U and W agree on a dense subset of their initial space, so $U = W$. \square

Double Commutant Theorem

Definition: Let $M \subseteq B(H)$. We define the *commutant* to be

$$M' := \{S \in B(H) \mid TS = ST \text{ for all } T \in M\}.$$

The double commutant of M is denoted M'' , and has $M \subseteq M''$.

We see that M' is a WOT-closed subalgebra, and if M' is self-adjoint, then M' is a C^* -algebra. Addition-

ally, if $M_1 \subseteq M_2$, then $M'_1 \supseteq M'_2$.

Theorem (Double Commutant Theorem): Let M be a unital C^* -subalgebra of $B(H)$. The following are equivalent:

- (i) $M = M''$;
- (ii) M is WOT-closed;
- (iii) M is SOT-closed.

Proof. The implications (i) implies (ii) follows from the discussion above, and (ii) if and only (iii) follow from the definitions (as subalgebras are convex). We focus on showing that (iii) implies (i).

For a fixed $\xi \in H$, let P be the projection onto the closure of the subspace $\{T\xi \mid T \in M\}$. We see that $P\xi = \xi$, since $I_H \in M$. Additionally, $PTP = TP$ for each $T \in M$, so $P \in M'$. Letting $V \in M''$, we have that $PV = VP$, so $V\xi \in PH$. In particular, for each $\varepsilon > 0$, there is $S \in M$ such that $\|(V - S)\xi\| < \varepsilon$.

Let $\xi_1, \dots, \xi_n \in H$, and set $\xi = (\xi_1, \dots, \xi_n)$ in $H^{(n)}$. Letting $\rho: B(H) \hookrightarrow B(H^{(n)})$ be the embedding defined by

$$T \mapsto T^{(n)},$$

we see that

$$\rho(M)' = \{S \in B(K) \mid S_{ij} \in M'\}.$$

Therefore, we have that $\rho(V) \in \rho(M)''$, meaning that using the same process as above in the amplified algebra, we have

$$\begin{aligned} \sum_{k=1}^n \|(V - T)\xi_k\|^2 &= \|(\rho(V) - \rho(T))\xi\|^2 \\ &< \varepsilon^2, \end{aligned}$$

meaning that we can approximate V in SOT from M , so $V \in M$. □

Definition: A *von Neumann algebra* is a unital SOT-closed (or WOT-closed) C^* -subalgebra of $B(H)$.

The double commutant theorem says that $M = M''$ is a characterization of a von Neumann algebra.

Observe that if $T \in M$ is a normal operator in a von Neumann algebra M , then if E denotes the spectral measure for T , and $S \in M'$, then $TS = ST$, so by Fuglede's Theorem, $T^*S = ST^*$, meaning that $Sf(T) = f(T)S$ for all $f \in B_\infty(\sigma(T))$. In particular, this means that $E(S) \in M'' = M$. Since the closed linear span of the characteristic functions χ_S is equal to $B_\infty(\sigma(T))$, it follows that, if M is a von Neumann algebra, then M is the (norm)-closed linear span of all of its projections.

To see this another way, let $a \in M_{\text{s.a.}}$, and consider a partition $-\|a\| = t_0 < t_1 < \dots < t_n = \|a\|$, where $t_{j+1} - t_j < \varepsilon$ for each $j = 0, \dots, n-1$, and define projections

$$P_i = \chi_{[t_{j-1}, t_j)}$$

for $j = 1, \dots, n-1$, and $P_n = \chi_{[t_{n-1}, t_n]}$. Then, we necessarily have

$$\left\| a - \sum_{j=1}^n t_j P_j \right\|_{\text{op}} < \varepsilon,$$

so every self-adjoint operator is in the norm-closed linear span of the projections of M . Since every element of M can be written as a decomposition of self-adjoint operators, it follows that M is the norm-closed linear span of its projections.

Proposition: Let M be a von Neumann algebra, and let $A \in M$.

- (a) If A is normal, and ϕ is a bounded Borel function on $\sigma(A)$, then $\phi(A) \in M$.
- (b) The operator A is the linear combination of four unitaries in M .
- (c) If E and F are the projections onto $\overline{\text{im}(A)}$ and $\ker(A)$ respectively, then $E, F \in M$.
- (d) If $A = W|A|$ is the polar decomposition for A , then W and $|A|$ are in M .

Abelian von Neumann Algebras

Definition: Two subsets $M_1 \subseteq B(H_1)$ and $M_2 \subseteq B(H_2)$ are said to be *spatially isomorphic* if there is an isomorphism $U: H_1 \rightarrow H_2$ such that $UM_1U^{-1} = M_2$.

Definition: A vector e_0 is said to be separating for $S \subseteq B(H)$ if the only operator for which $Se_0 = 0$ is the 0 operator.
