**Problem** (Problem 1): Given  $z = x + iy \in \mathbb{C}$ , define

$$z^* = \left(\frac{2x}{x^2 + y^2 + 1}, \frac{2y}{x^2 + y^2 + 1}, \frac{x^2 + y^2 - 1}{x^2 + y^2 + 1}\right).$$

- (a) Show that  $z^* \in S^2$ .
- (b) Prove that if  $(x_1, x_2, x_3) \in S^2 \setminus \{(0, 0, 1)\}$ , then there exists a unique  $z \in \mathbb{C}$  such that  $z^* = (x_1, x_2, x_3)$ .
- (c) A circle in  $S^2$  is the intersection of a plane in  $\mathbb{R}^3$  with  $S^2$ , provided this intersection is nonempty. Prove that if C is a circle in  $S^2$ , then there exists a set  $\widetilde{C} \subseteq \mathbb{C}$  that is either a circle or a straight line such that  $C \setminus \{(0,0,1)\} = \left\{z^* \in \mathbb{R}^3 \mid z \in \widetilde{C}\right\}$ .

## Solution:

(a) Via brute force calculation, we see that

$$\frac{4x^{2}}{(x^{2}+y^{2}+1)^{2}} + \frac{4y^{2}}{(x^{2}+y^{2}+1)^{2}} + \frac{(x^{2}+y^{2}-1)^{2}}{(x^{2}+y^{2}+1)^{2}} = \frac{(x^{2}+y^{2})^{1}+1-2(x^{2}+y^{2})+4(x^{2}+y^{2})}{(x^{2}+y^{2}+1)^{2}}$$

$$= \frac{(x^{2}+y^{2})^{1}+1+2(x^{2}+y^{2})}{(x^{2}+y^{2}+1)^{2}}$$

$$= 1.$$

(b) Let  $z^* = (x_1, x_2, x_3) \in S^2 \setminus \{(0, 0, 1)\}$ , and let L:  $[0, \infty) \to \mathbb{R}^3$  be the line parametrized such that  $L(1) = (x_1, x_2, x_3)$  and L(0) = (0, 0, 1), which is given by

$$L(t) = (tx_1, tx_2, tx_3 + (1 - t)).$$

Note then that ||L(t)|| = 1 only when t = 0 or t = 1, meaning that L(t) intersects  $S^2 \setminus \{(0,0,1)\}$  exactly once. By identifying  $\mathbb C$  with  $x + iy \mapsto (x,y,0)$ , we may find  $z \in \mathbb C$  that uniquely maps to  $(x_1,x_2,x_3)$  under the  $z^*$  identification by taking

$$tx_3 + (1 - t) = 0$$
$$1 + t(x_3 - 1) = 0$$
$$t = \frac{1}{1 - x_3}$$

so that

$$x + iy = \frac{x_1}{1 - x_3} + i \frac{x_2}{1 - x_3}$$

maps to  $z^*$  under the given identification.

(c) Let  $(x_1, x_2, x_3) \in S^2$  lie on the plane  $ax_1 + bx_2 + cx_3 = d$ . By substituting  $z = x + iy \mapsto z^*$ , we get

$$a\frac{2x}{x^2 + y^2 + 1} + b\frac{2y}{x^2 + y^2 + 1} + c\frac{x^2 + y^2 - 1}{x^2 + y^2 + 1} = d$$

$$2ax + 2by + c(x^2 + y^2 - 1) = d(x^2 + y^2 + 1)$$

$$(c - d)x^2 + 2ax + (c - d)y^2 + 2by = c + d.$$

This gives two cases. If c = d, then we get the line

$$ax + by = c$$
.

Else, if  $c \neq d$ , we get the circle

$$x^{2} + \frac{2a}{c - d}x + y^{2} + \frac{2b}{c - d}y = \frac{c + d}{c - d}$$
$$\left(x - \frac{a}{c - d}\right)^{2} + \left(y - \frac{b}{c - d}\right)^{2} = \frac{a^{2} + b^{2} + c^{2} - d^{2}}{(c - d)^{2}}.$$

Thus, circles in  $S^2$  correspond to either circles or lines in  $\mathbb{C}$ .

**Problem** (Problem 2): Define  $f: \mathbb{C} \setminus \{1\} \to \mathbb{C}$  by  $f(z) = \left(\frac{z+1}{z-1}\right)^2$ .

- (a) Is f injective on D? Why or why not?
- (b) Determine  $f(\mathbb{D})$ .

## **Solution:**

(a) We consider  $q(z) = \frac{z+1}{z-1}$  as a fractional linear transformation on  $\hat{\mathbb{C}}$ . We see that

$$\begin{split} q(e^{i\theta}) &= \frac{e^{i\theta} + 1}{e^{i\theta} - 1} \\ &= \frac{(1 + \cos(\theta)) + i\sin(\theta)}{(\cos(\theta) - 1) + i\sin(\theta)} \\ &= \frac{((\cos(\theta) + 1) + i\sin(\theta))((\cos(\theta) - 1) - i\sin(\theta))}{(1 - \cos(\theta))^2 + \sin^2(\theta)} \\ &= \frac{(\cos^2(\theta) - 1) + \sin^2(\theta) + i\sin(\theta)(\cos(\theta) - 1 - (\cos(\theta) + 1))}{2 - 2\cos(\theta)} \\ &= i\frac{\sin(\theta)}{\cos(\theta) - 1} \end{split}$$

and since  $\frac{\sin(\theta)}{\cos(\theta)-1}$  maps  $(0,2\pi)$  to  $\mathbb R$  bijectively, we see that q maps  $S^1\setminus\{1\}$  into the imaginary axis. We also see that q(0)=-1, so q maps  $\mathbb D$  bijectively onto the left half-plane,  $\mathbb L=\{z\mid \mathrm{Re}(z)<0\}$ , as Möbius transformations are unique.

Now, notice that the function  $h(z) = z^2$  is injective when defined on a half-plane, as the arguments  $(\pi/2, 3\pi/2)$  map injectively to  $(\pi, 3\pi)$ , and the function  $|z|^2$  is clearly injective on  $(0, \infty)$ , so  $f = h \circ q$  is injective on  $\mathbb{D}$ .

(b) Since  $f = h \circ q$ , where q maps  $\mathbb{D}$  to the left half-plane, and h maps the left half-plane to the full complex plane save for  $(-\infty, 0]$ , as the imaginary axis is excluded from  $q(\mathbb{D})$ , and so we have that f maps  $\mathbb{C}$  to  $\mathbb{C} \setminus (-\infty, 0]$ .

**Problem** (Problem 3): Prove that there exists a linear fractional transformation that maps the first quadrant in  $\mathbb{C}$  bijectively to the top half of the unit disc, and satisfies f(2) = i.

Solution: We start from the Cayley transform,

$$f_1(z) = \frac{z - i}{z + i},$$

which bijectively maps the upper half-plane to the unit disc. By taking z = x + iy for x, y > 0, we see that

$$f_1(x + iy) = \frac{1}{x^2 + (y + 1)^2} ((x^2 + y^2 - 1) + i(-2x)),$$

implying that the first quadrant is mapped to the *lower* half of the unit disc. Therefore, we flip about the

origin by taking  $f_2(z) = -f_1(z)$ , so that

$$f_2(z) = -\frac{z - i}{z + i},$$

which maps the first quadrant of the upper half plane to the top half of the unit disc. Next, we see that

$$f_2(1) = -\frac{1-i}{1+i}$$
  
= i,

so to ensure that f(2) = i, we may define  $f(z) = f_2(z/2)$ , or

$$f(z) = -\frac{z - 2i}{z + 2i}.$$

**Problem** (Problem 4): Let  $f: \mathbb{C} \to \mathbb{C}$  be a function. We say that  $\lim_{z\to\infty} f(z) = \infty$  if, for all M > 0, there exists R > 0 such that |f(z)| > M whenever |z| > R.

- (a) Show that if  $f: \mathbb{C} \to \mathbb{C}$  is a nonconstant polynomial, then  $\lim_{z\to\infty} f(z) = \infty$ .
- (b) Suppose that  $f: \mathbb{C} \to \mathbb{C}$  is a continuous function satisfying  $\lim_{z\to\infty} f(z) = \infty$ . Show that there exists some  $z_0 \in \mathbb{C}$  for which  $|f(z_0)| = \inf_{z\in\mathbb{C}} |f(z)|$ .

## Solution:

(a) If  $f(z) = \sum_{k=0}^{n} a_k z^k$ , with n > 1 and  $a_n \neq 0$ , then by a corollary of the triangle inequality, we see that

$$|f(z)| = \left| \sum_{k=0}^{n} a_k z^k \right|$$
$$\ge |a_n z^n| - \sum_{k=0}^{n-1} |a_k z^k|.$$

Now, we notice a few things. First, since  $|a_n|$  is nonzero, we may divide by  $|a_n|$ , giving

$$\frac{1}{|a_n|}|f(z)| \ge |z|^n - \frac{1}{|a_n|} \sum_{k=0}^{n-1} |a_k||z|^k.$$

Now, from real analysis, we know that

$$\lim_{|z|\to\infty}|z|^n=\infty,$$

as we may select  $R = M^{1/n}$  to achieve this purpose. So, by using the limit comparison test, we see that

$$\lim_{|z| \to \infty} \frac{|z|^n - \sum_{k=0}^{n-1} |a_k/a_n| |z|^k}{|z|^n} = 1,$$

so

$$\lim_{|z|\to\infty}\frac{1}{|a_n|}|f(z)|=\infty,$$

so

$$\lim_{z \to \infty} |f(z)| = \infty.$$

(b) Let M > 0 be sufficiently large such that the set  $\{z \in \mathbb{C} \mid |f(z)| \le M\}$  is not empty. Since  $\lim_{z \to \infty} f(z) = \infty$ , there exists R such that |f(z)| > M whenever |z| > R.

We see that on B(0, R), the closed disk of radius R centered at 0, the function f is continuous, and so is the function |f(z)|, as the modulus is also a continuous function. Since B(0, R) is compact, there is some  $z_0 \in B(0,R)$  such that  $|f(z_0)| = \inf_{z_0 \in B(0,R)} |f(z)|$ . In particular, we note that  $|f(z_0)| \le M$ , as we have specifically selected M to be such that  $\{z \in \mathbb{C} \mid |f(z)| \le M\}$  is nonempty, meaning that  $|f(z_0)| = \inf_{z \in \mathbb{C}} |f(z)|$ , as we have selected R such that  $|f(z_0)| > M$  for all  $z \in \mathbb{C} \setminus B(0,R)$ .
