The basis of Multivariable Calculus

If a function is continuous and differentiable, on a small enough interval, the function will approximate a line (i.e., a function of x).

A similar intuition applies to functions of more than one variable (but with a plane, cube, hypercube, etc.). However, in multivariable functions, we will have to sacrifice the ability to visualize it.

For example, in multiple dimensions, it is possible for there to be a function that is both strictly decreasing (in one dimension) and strictly increasing (in another dimension).

Some Functions and Sets

$$f(x,y) = x^2 - y^2$$

Domain: $\{(x,y) \mid \exists f(x,y)\}$

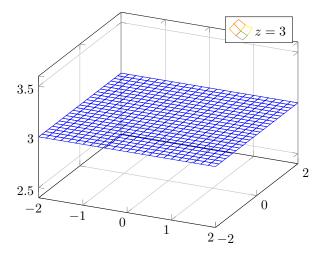

Range: $\{f(x,y) \mid (x,y) \in Dom(f)\} = \mathbb{R}$

GRAPH: Graph $(f) = \{x, y : f(x, y) \mid x, y \in \text{Dom}(f)\}$. For example, $(1, 3, 4) \notin \text{Graph}(f)$ since $1^2 - 3^2 \neq 4$.

Examples

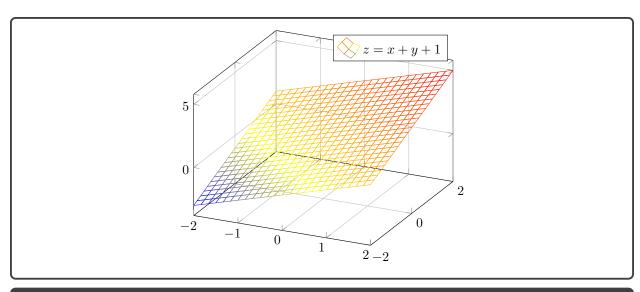

In \mathbb{R}^3 , in x, y, z coordinates, z = 3 is a plane defined as follows:

- \bullet Parallel to the xy plane.
- Passes through the point (0.0, 3).

Meanwhile, y = 0 would be a "wall" that passes through the origin that contains the line y = 0 in the xy plane.

Finally, z = x + y + 1 is a plane, as we can see below.

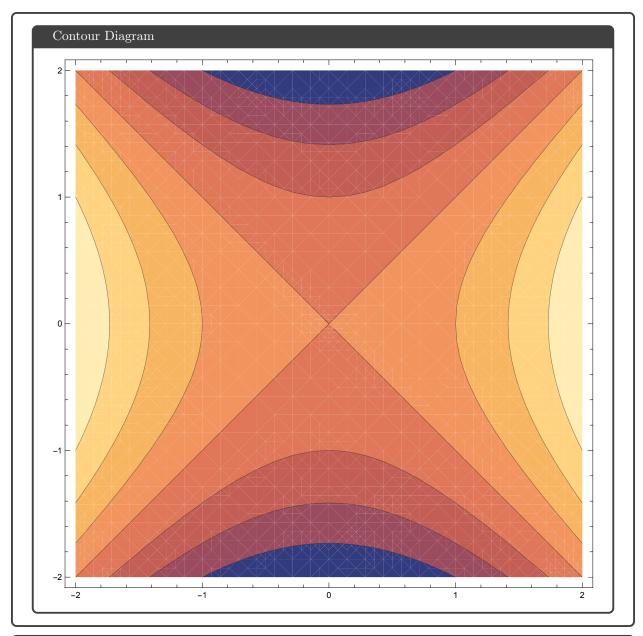

Visualizing a function of multiple variables

Consider the function $f(x,y) = x^2 - y^2$. We can try visualizing slices as follows:

- $f(-2,y) = 4 y^2$
- $f(0,y) = -y^2$
- $f(2,y) = 4 y^2$
- $f(x,-2) = x^2 + 4$
- $f(x,0) = x^2$
- $f(x,2) = x^2 + 4$

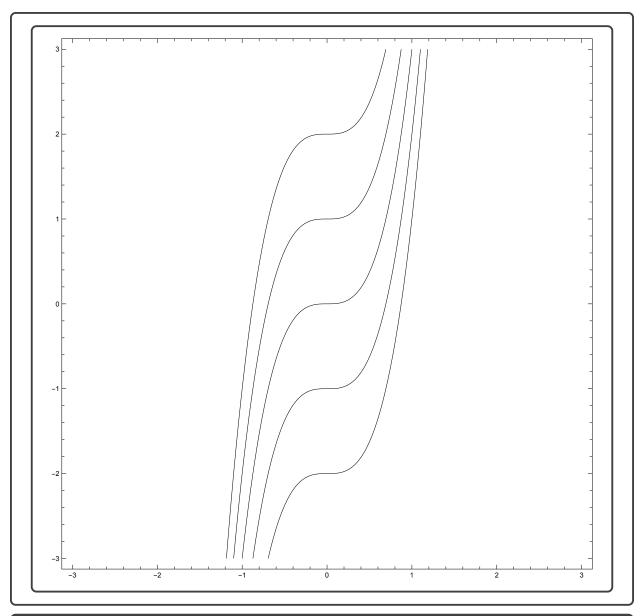

Alternatively, we can visualize via contour diagrams (i.e., everywhere that z is a certain value), as seen in mathematica as follows:

Contour Example

Consider the function $f(x,y) = y - 3x^2$. We want to find the contours.

For any c, we have that $c=y-3x^3$, or $y=3x^3+c$. Therefore, every contour "looks like" $3x^3+c$ for values of c. For example, in the following, we have $c=\{-2,-1,0,1,2\}$

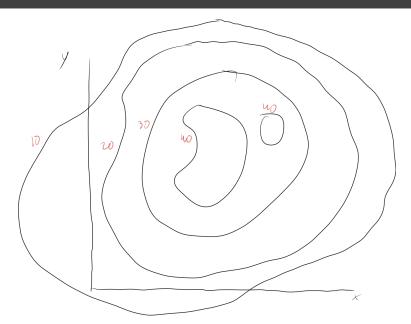

Distance

In \mathbb{R}^5 , let p=(3,1,4,1,5), and q=(1,0,-2,0,2). Using the Euclidean metric, we can find the distance between p and q is $d(p,q)=((3-1)^2+(1-0)^2+(4-(-2))^2+(1-0)^2+(5-2)^2)^{1/2}=(4+1+36+1+9)^{1/2}=\sqrt{51}=7.14$. We can also call this the 2-norm.

$$d(p,q) = \left(\sum_{k=1}^{n} (p_k - q_k)^2\right)^{1/2}$$

Derivatives

To denote a derivative, we can't talk about one value, we must use a partial derivative, $\frac{\partial f}{\partial x}$, or $\frac{\partial f}{\partial y}$. The closeness of the contours specifies both resolution and steepness.

We can estimate slope by calculating the difference between two contours, divided by the distance between them along a path.

We can also analyze via a table:

A "linear" approximation for a function of two variables is expressed as follows:

$$z - z_0 = m(x - x_0) + n(y - y_0)$$

Where $(x_0, y_0, z_0) \in \mathbb{R}^3$, and is an output in z = f(x, y), and $m, n \in \mathbb{R}$.

For example, with the above table, we can see that the function is linear in x and y (i.e., the slope holding the other variable constant is constant).

Limits in Multivariable Functions

Consider the following:

$$\lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{x^2-y^2}$$

Allow y = mx

$$\lim_{(x,y)\to(0,0)} \frac{x^2 + y^2}{x^2 - y^2} = \lim_{(x,y)\to(0,0)} \frac{x^2 + (mx)^2}{x^2 - (mx)^2}$$
$$= \frac{1 + m^2}{1 - m^2}$$

Thus, the limit must depend on the path taken. The following table shows the limits for different values of m

$$\begin{array}{c|c} m & \lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{x^2-y^2} \\ \hline 0 & 1 \\ 1 & \text{undefined} \\ 2 & -\frac{5}{3} \end{array}$$

Because the limit depends on the path of incidence, we have that the limit is undefined.

For graphs where the contours "approach" a particular point, we can see that the limit is defined.

Vectors

A vector is a mathematical object with direction and magnitude:

$$\vec{v} = \begin{bmatrix} 3 \\ 1 \\ 4 \end{bmatrix}$$

Alternatively, we can have $\vec{w} = \begin{bmatrix} 3 & 1 & 4 \end{bmatrix}$. These vectors are equivalent because they are components of \mathbb{R}^3 .

Vector addition is *component-wise*, (i.e., you add or subtract components in order to find the new vectors).

Direction of \vec{v}

$$\frac{\vec{v}}{\|\vec{v}\|}$$

Properties of Vectors

Let $\vec{u}, \vec{v} \in \mathbb{R}^n$. Via properties of the real numbers, we know the following:

- $\bullet \ \vec{u} + \vec{v} = \vec{v} + \vec{u}$
- $(\vec{u} + \vec{v}) + \vec{w} = \vec{u} + (\vec{v} + \vec{w})$
- $c\vec{u} = \langle cu_1, cu_2, \dots, cu_k \rangle$

Additionally, we define $\vec{u} \cdot \vec{v}$ as follows:

$$\vec{u} \cdot \vec{v} = \sum_{k=1}^{n} u_k v_k = ||\vec{u}|| ||\vec{v}|| \cos \theta$$
